Quinine Hypophosphite. [$C_{20}H_{24}O_2N_2HPH_2O_2 + 2H_2O = 426.31$]. *Quininæ Hypophosphis. N. F. IV.*—"The hypophosphite of the akaloid quinine. Preserve it in well-stoppered, amber-colored bottles." *N. F. IV.* "Quininde Hypophosphite occurs as fine, white, silky, glistening needles or prisms; odorless and having a very bitter taste. One gramme dissolves in about 35 mils of water, in 12.5 mils of alcohol, or in 27 mils of chloroform at 25° C.; almost insoluble in ether. Heated to 100° C., Quinine Hypophosphite becomes anhydrous; the anhydrous salt melts at about 181° C. At a higher heat it fuses to a black mass and evolves vapors of phosphuretted hydrogen. Incinerate 0.2 Gm. of the salt; no weighable residue remains. Add 1 mil of bromine T.S. to 10 mils of an aqueous solution of the salt (1 in 1000) and then follow with 1 mil of ammonia water; the liquid acquires an emerald-green color. Acidulate an aqueous solution of the salt (1 in 40) with a few drops of nitric acid, add silver nitrate T.S. and warm the liquid; a brown precipitate is formed, which, on standing, becomes black. Dissolve 0.1 Gm. of the salt in 10 mils of distilled water, and add a few drops of nitric acid; the solution is not rendered more than faintly turbid by the addition of silver nitrate T.S. (*chloride*). Dissolve 0.1 Gm. of the salt in 10 mils of distilled water, and add a few drops of hydrochloric acid; the solution is not rendered more than faintly turbid by the addition of barium chloride T.S. (*sulphate*). To test this salt for excessive amounts of *other cinchona alkaloids* proceed as directed under *Quininæ Glycerophosphas." N. F. IV.* This hypophosphite was admitted to the N. F. IV to be used in the *compound solution of hypophosphites.* The *dose* is the same as that of quinine sulphate.

Quinine Iodate. *Quininæ Iodas.* $C_{20}H_{24}O_2N_2.HIO_3$.—Made by dissolving freshly precipitated quinine in hydriodic acid, using molecular proportions, and afterwards evaporating and drying the salt. In small needle-like crystals, freely soluble in alcohol and in 700 parts of cold water. It contains about 63 per cent. of quinine.

Quinine Phenolsulphonate. *Quininæ Phenolsulphonas. Quinine Sulphocarbolate.* $C_{20}H_{24}O_2N_2[C_6H_4(OH)SO_3H]$.—Made by precipitating 10 parts of quinine sulphate, in 500 parts of water, by adding it to a boiling solution of 6 parts of barium phenolsulphonate, dissolved in 75 parts of water. The precipitate is washed and dried. A yellowish-white mass, melting when warmed, only slightly soluble in water, soluble in alcohol.

Quinine Sulphoguaiacolate. *Quinine Orthoguaiacol-sulphonate. Sulphoguaiacin.*—This occurs in yellowish, crystalline leaflets freely soluble in water but only sparingly so in alcohol or ether. It is stated to be actively antiseptic and is used in the treatment of various infectious diseases, as *influenza, tuberculosis, rheumatic fever, whooping cough,* etc. It is usually given either hypodermically or in suppository. The single *dose* should not exceed six to eight grains (0.4–0.5 Gm.), but it is stated that sixty grains (3.9 Gm.) may be given in the twenty-four hours.

Quinine Valerate. [$C_{20}H_{24}O_2N_2HC_5H_9O_2 + H_2O = 443.30$]. *Quininæ Valeras. N. F. IV.*—"The valerate of the alkaloid quinine. Preserve it in well-stoppered, amber-colored bottles." *N. F. IV.* "Quinine Valerate occurs as white, lustrous crystals, having an odor of valeric acid and an intensely bitter taste. It is sparingly soluble in cold water, soluble in hot water, becoming less soluble with age on account of loss of valeric acid; readily soluble in alcohol. Its aqueous solution is neutral or slightly alkaline to litmus. Add a few drops of bromine water to 10 mils of an aqueous solution of the salt (1 in 1000), then add an excess of ammonia water; an emerald-green color is produced. An aqueous solution of the salt, acidulated with sulphuric acid, exhibits a blue fluorescence and has the odor of valeric acid. Incinerate 1 Gm. of Quinine Valerate; not more than 0.1 per cent. of ash remains. About 0.1 Gm. of the salt dissolves in 5 mils of sulphuric acid without producing more than a light yellow color (*readily carbonizable impurities*). Ten mil portions of the cold, saturated aqueous solution of the salt do not give more than a slight turbidity with barium chloride T.S. when acidulated with hydrochloric acid (*sulphate*); nor with silver nitrate T.S. when

acidulated with nitric acid (*chloride*). To test this salt for excessive amounts of *other cinchona alkaloids* proceed as directed under *Quininæ Glycerophosphas.*" *N. F. IV.* This quinine salt was admitted to the National Formulary IV to be used as an ingredient in *Elixir of Quinine Valerate and Strychnine.* The amount of valeric acid in this elixir is entirely too small to have any therapeutic action and this criticism applies to the salt itself which is given in the same dose as quinine sulphate.

Quinoa.—The *Chenopodium Quinoa* Willd. (Fam. *Chenopodiaceæ*), is largely cultivated in Southern Peru and Southern Chili, often above the height at which barley and rye will ripen, for the sake of its seeds. These are about the size of white mustard seeds, but flatter, and afford a flour resembling somewhat oatmeal. The starch grains are very small, and constitute about 40 per cent. of the grain, which also contains 5 per cent. of sugar, 7½ of casein, and 11 of albumen and other protein compounds. One variety, the *red quinoa,* contains a bitter principle in the seed husks, and is used to some extent as an emetic and antiperiodic. (*A. J. P.*, 1872, 559.)

Quinoline. *Chinoline. Leucoline. Chinolin,* G. (C_9H_7N.)—This is an artificial alkaloid prepared by the destructive distillation of quinine or cinchonine with potassium hydroxide, and also synthetically by König's and Skraup's processes by the action of sulphuric acid and glycerin upon nitrobenzene and aniline, or a mixture of these two latter substances. *Chinoline* is a colorless, strongly refractive, oily liquid, having a specific gravity of 1.081 at 10° C. (50° F.) (Hoffmann), boiling at 235.6° C. (456.8° F.) without decomposition, the oily stain left on bibulous paper disappearing readily on exposure. Its odor is aromatic, resembling that of oil of bitter almond. It is sparingly soluble in cold water, more so in hot water, soluble in alcohol, and mixes in all proportions with ether, carbon disulphide, methyl alcohol, etc. It easily dissolves camphor and resin. It gradually turns reddish-brown in color on exposure to the air. It forms readily crystallizable salts with acids, the tartrate now being a commercial article; these salts are decomposed by contact with fixed alkalies and the peculiar odor of quinoline developed. Ekin (*P. J.*, Feb. 11, 1882) found a sample of commercial German chinoline to consist largely of a mixture of aniline and nitrobenzene, although labelled pure. *Quinoline tartrate,* $(C_9H_7N)_3.(C_4H_6O_6)_4$, is in the form of a whitish, micaceous, crystalline powder, melting at 125° C. (257° F.). It dissolves in 80 parts of cold water, in about 150 parts of alcohol, and in 300 parts of ether, having a peculiar pungent odor and a rather sharp, though not unpleasant taste. *Quinoline hydrochloride,* $C_9H_7N.HCl$, melts at 94° C. (201.2° F.) and sublimes unchanged. It dissolves in water, alcohol, and chloroform. *Quinoline salicylate,* $C_9H_7N.C_7H_6O_3$, is a white crystalline powder, soluble in water and glycerin, very soluble in alcohol, ether, vaseline, and fatty oils.

While quinoline was originally brought forward as a substitute for quinine, experience has shown that it possesses only feeble antiperiodic properties. It is, however, an active antipyretic and is also a powerful germicide. It is a depressant to the central nervous system and in 1 per cent. solution will prevent the coagulation of the blood. It is used chiefly as an antiseptic, especially in the treatment of *gonorrhea* for which purpose an 0.7 per cent. solution may be employed. Quinoline has been highly commended as a preservative for anatomical specimens. The formula adopted in the Erlangen Physiological Institute is: quinoline, 5 grammes; sodium chloride, 6 grammes; glycerin, 100 grammes; water, 900 grammes. The ordinary tar quinoline can be used. For physiological study of quinoline derivatives, see *Trans. College of Physicians of Edinburgh* (Laboratory), 1893; also Laidlaw (*Biochem. J.*, 1910, v, 243).

Quinoline Sulphocyanate or **Rhodanate.** *Quinine thiocyanate. Quinolinæ Sulphocyanas.*—A colorless or yellowish, crystalline powder, only slightly soluble in cold water and ether, but freely soluble in hot water and alcohol. The salt melts at about 137° C. (278.6° F.).

Radium. Ra = 226.4.—The discovery that certain substances are radio-active was made by Henri Becquerel in 1896, who showed that *uranium* was capable of affecting a photographic plate in the same way as light. Shortly after this, it was shown that a number of other substances were radio-active. The characteristics of radio-active bodies are four: (1) They affect photographic plates; (2) they produce phosphorescence in certain substances; (3) they cause the surrounding air to become a conductor of electricity; (4) they produce heat. In 1899 Madame Curie, while investigating the radio-activity of certain minerals, came to the conclusion that the uranium ore, known as *pitchblende,* must contain some substance more actively radiant than uranium itself. This led her to the separation of the element radium, which showed two million (2,000,000) times as much activity as uranium.

Radium is an elemental substance, possessing remarkable chemical and physical properties, discovered in pitchblende, a complex uranium ore, by Professor and Madame Curie of the University of Paris, in 1900.

After tedious and difficult experimentation involving the recrystallization, precipitation, and concentration of a ton of the ore down to a few decigrammes of purified product, a barium-like element was discovered which was many thousand times as active as uranium in its radio-activity, and which was therefore named radium by its discoverers. Radium is manufactured in several places in America at the present time, thus putting a stop to the shipment of uranium ores to Europe. The United States Government has taken an active interest in locating deposits of uranium bearing ores. The most valuable deposits have been found in Colorado so far. In testing specimens of unknown ores for radio-activity, the photographic plate is used and an exposure is made of the unopened plate with a small metal object placed between the ore sample and the plate. After leaving the objects in this relative position for twelve hours or more the plate is developed in the regular way and is examined for evidence of a photographic outline or image of the metal object. The extraction of radium salts from pitchblende and *carnotite,* another radium containing uranium ore, includes three stages. First the ores are roasted; the roasted ores are then treated with sulphuric and nitric acids which takes out the uranium compounds and leaves the radio-active metals behind as sulphates; the residue is then treated alternately with alkalies and acids and is finally separated by fractional precipitation as sulphate.

One ton of uranium residues furnishes from 17 to 22 pounds of radio-active barium residue, which upon final concentration yields a few drachms of

radium bromide of high radio-active power. The element radium has not yet been obtained.

Properties.—Radium gives off three groups of rays, which are known by the first letters of the Greek alphabet, *alpha*, *beta*, and *gamma rays*. The alpha and beta rays are universally acknowledged to be material substances, while the gamma rays are by some considered waves of ether, and by others as electrons. Besides these, in solution radium liberates a gaseous element which is known as *emanation*. This gas is formed in the radium while in the dry state, but is completely absorbed, and only given off from solutions of salts of the metal. The most widely accepted theory concerning the origin of these rays is that of Rutherford. According to this, radio-activity is a sign of atomic destruction, particles of matter being given off, and the element being changed into another form of element with a lower molecular weight. Thus, uranium gives off alpha particles, and the residue is *ionium;* this gives off alpha particles, the residue being radium. The decomposition of radium forms emanation, which in turn gives off alpha particles, forming a series of active deposits known as Radium A., Radium B., C., D., E., F. (Polonium), and eventually Radium G., which is by some believed to be identical with lead.

The alpha rays, which constitute about nine-tenths of the radiation of radium are positively charged electrons with a mass about four times that of hydrogen, moving with a velocity approximately one-tenth that of the light wave. By some they are supposed to be identical with the element *helium*, or rather to represent helium in the process of formation. Their power of penetration is relatively small. They can pass only through three inches of air, and are stopped by a heavy sheet of note-paper.

The beta rays are negatively charged electrons, and are by many believed to be identical with the cathode stream formed in a Crooke's tube. Their velocity is about equal to that of light, and their penetration is quite considerable, it requiring a sheet of lead one centimeter in thickness to certainly stop them.

The gamma rays form only about one per cent. of the total radiation. Of their nature comparatively little is known. Their penetration is extraordinary, exceeding that of the X-ray. Because of the fact that they are not deflected by a magnetic field it was formerly believed that they were non-material, but the theory has been brought forward that they are discrete particles, electrically neutral.

Emanation is constantly being formed in radium. It is absorbed by the salts of the metal when in a dry state, but is liberated when the salt is dissolved. It is a gaseous element, which may be liquefied at a temperature of −150° C. (−238° F.), and has an atomic weight of 222. When freshly liberated it is radio-active, but becomes exhausted within a relatively short time, one-half of its power being dissipated within four days. Any substance exposed to emanation becomes temporarily radio-active. This is due to a deposit of the solid matter into which emanation is transferred after giving off its alpha rays.

The approximate estimate of the radio-active power in given substances can be reached by the degree of its influence upon photographic plates or the degree of fluorescence imparted to a platinocyanide screen, but accurate measurements are based upon their ionizing power, that is, upon the degree of electrical conductivity they impart to the air. For this purpose, an apparatus known as the electroscope is employed. A *Curie* is the amount of emanation in equilibrium with one gramme of radium. A micro-curie is one-millionth of this and is equivalent to the amount of emanation in one milligramme of radium and equals 2500 "Maché units."

Most of the radium which is used therapeutically is in a more or less impure state, and it becomes necessary to have some knowledge of the radio-active power of any known specimen before it is used for medical purposes. Manufacturers of radium generally supply with each sample of the metal, a statement of its power, in which uranium is taken as the unit. For instance, pure radium has two million units, that is, it is two million times as radio-active as uranium. Specimens of over two-hundred-thousand units are suitable for medical uses.

Therapeutic Uses.—The medical value of radium depends in the first place upon the destructive action of the rays upon the certain pathological tissues, and secondly upon the alterations in functions which are produced by the internal administration of emanation. The widest use of radium has been as a destructive agent in various types of *neoplasms*. For this purpose it is applied in various forms of containers, the most popular being a sealed glass tube, which is enclosed within a thin aluminum capsule to protect it from breaking.

The earliest investigations of the action of radium rays upon living protoplasm appear to be those of Schwarz (*A. G. P.*, 1903), who showed that when hen's eggs were exposed to the metal there was a decomposition of the lecithin within them. London (*B. K. W.*, xliii) found that rabbits kept for two weeks in a cage on top of which was placed 25 mgm. of radium lost their hair, the ears necrosed and the sexual organs degenerated; he believes that the emanations have no effect on fibroid tissue. The alpha rays have considerable germicidal action, as apparently does also emanation, but neither of these have any great penetrative power, so that the anti-bacterial effect of radium is not likely to prove of practical utility.

When applied to the skin, radium produces no immediate effect, but lesions appear after considerable periods of incubation, which may be as long as two weeks. If the dose has been small there is merely redness, but after longer exposure an ulcer is formed which heals very slowly. Although there is left behind, when these ulcers heal, a white supple cicatrix, destruction to the hair folicles, sweat and subaceous glands may have been the result of the action of the rays upon the skin. It is possible, however, to profoundly influence the deeply lying structures with much less danger of causing dermatological injuries than with the X-rays. This can be accomplished by screening off the relatively superficially acting alpha and beta rays which allows the deeply penetrating gamma rays alone to act.

Radium has been used for the destruction of various *malignant growths*, and in a number of cases with good results. In any form of malignant tumor, however, in which operation is possible, while the radium treatment may be useful as an adjunct to the surgical, it should never offer an excuse for delaying operative interference. When, however, for any reason operation is impossible, the use of radium holds out hope for symptomatic relief, and in a certain proportion of cases, even for complete recovery. In the first

annual report of the London Radium Institute (*B. M. J.*, Jan. 25, 1913, p. 149), of 38 cases of *cancer of the breast* 35 were improved by the treatment, although in only a few instances did the carcinomous nodules disappear. In 39 cases of inoperable *cancer of the uterus* there were three apparently cured while in 19 there was relief of pain and arrest of the discharge and hemorrhage. The most striking results are obtained in cases of *rodent ulcers*. In these, provided the bones or cartilages have not been attacked, and the mucous membrane is not involved, strong hope for a complete cure may be held out. Out of 90 cases treated in the London Institute, 31 were apparently cured, and 41 improved. In *sarcoma* also, markedly beneficial results are often obtained. Other conditions in which benefit is sometimes seen from the radium treatment includes *lupus erythematosus, keloid, tuberculous glands, pruritus, leukemia,* and *nevi*. For further information on the use of radium in cancer, see symposium in *J. A. M. A.*, 1914, lxiii, p. 737. The dosage of radium is generally expressed in terms of pure radium and time. For instance, if the quantity of the salts equivalent to one milligramme of pure radium is to be applied for one hour, the dosage set is "one milligramme, hour." If an impure preparation is employed, as is usually the case, its activity must be calculated to that of pure radium. For instance, if the salt represent five-hundred-thousand units, it would require four milligrammes to exercise the same effect as one milligramme of pure radium.

Emanation when introduced into the system appears to have an influence upon the circulation, but especially upon metabolism. According to Loewi (*B. K. W.*, 1912, xlix, p. 198), the inhalation of emanation produces a contraction of the vessels of the lungs, and dilation of the vessels of the brain, with some tendency to lower the general blood pressure. The effect upon metabolism is shown in an increased elimination of uric acid. Although His (*B. K. W.*, xlviii, p. 197) found after the exhibition of radium marked diminution in the amount of uric acid in the blood, Fine and Chace (*J. P. Ex. T.*, 1914, vi, 219) could find no such change. Armstrong (*Practitioner*, 1912, lxxxviii, p. 156) and a number of German writers have described beneficial results from the drinking of water containing emanation, and also from the inhalation of the gas itself in *gout*.

While it seems evident that radium emanation has some marked effect on metabolism the precise nature of this alteration remains as yet obscure. Clinically, radium has been used internally in the treatment of *gout, arthritis deformans* and other diseases of the joints; in muscular *rheumatism,* in *sciatica, neuralgia* and other painful conditions. Some believe that the beneficial effects obtained by drinking mineral waters is due to their radium content; but while it is a fact that many of the famed medicinal springs are radio-active it remains to be shown that this explains their beneficial action. Indeed, the whole use of radium as an internal remedy is still in the experimental stage. An enumeration of the proprietary radium specialties, large numbers of which have been originated during the past few years, will be found in the *A. Ph. A. Year-book of Pharmacy*, 1912, p. 302.

Raisins. *Uva Passa. U. S.* 1870.—The dried ripe fruit of the *Vitis vinifera* L. (Fam. *Vitaceæ*), is no longer recognized by the Pharmacopœia. The grape vine itself is too well known to require description. Its leaves and tendrils are somewhat astringent, and were formerly used in *diarrhea, hemorrhages,* and other morbid discharges. The juice which flows from the stem was also thought to be possessed of medicinal virtues, and the idea still lingers among the vulgar in some countries. The unripe fruit has a harsh, sour taste, and yields by expression a very acid liquor, called *verjuice,* which was much esteemed by the ancients as a refreshing drink when diluted with water. It contains malic and tartaric acids, and an acid called *racemic acid,* a compound isomeric with tartaric acid, but differing from it in being optically inactive. M. A. Petit has ascertained that grape leaves contain 2 or 3 per cent. of glucose, and a quantity of acid varying from 1.3 to 1.6 per cent. Of the acid, tartaric acid constituted one-third, and most of this was in the form of cream of tartar. In a subsequent investigation, Petit found that the leaves contained a notable portion of both glucose and cane sugar. In one instance he obtained 1.58 per cent. of the latter and 1.749 of glucose. (*J. P. C.*, Jan., 1874, 41.) The seeds afford from 15 to 18 per cent. of a bland fixed oil, which is occasionally extracted. Fitz (*Ber. d. Chem. Ges.*, 1871, 442) has shown that it consists of the glycerides of *erucic acid,* $C_{22}H_{42}O_2$, stearic and palmitic acids, the first-named acid largely prevailing. The seeds further contained from 5 to 6 per cent. of tannic acid, which also exists in the skin of the fruit. The grape, when ripe, is among the most pleasant and grateful fruits, and is admirably adapted, by its refreshing properties, to febrile complaints. If largely taken, it proves diuretic and gently laxative. The ripe fruit differs from the unripe in containing more sugar and less acid, though never entirely destitute of the latter. The plant is a native of the southern shores of the Caspian Sea and Armenia, and has been cultivated in Europe and Northern Africa from the remotest antiquity, and is now spread over all the temperate civilized regions of the globe. The fruit is exceedingly influenced by soil and climate, and the varieties of the plant which have resulted from culture or situation are innumerable.

Several varieties of raisins are known in commerce. The best of the European fruit are the *Malaga raisins,* imported from Spain. They are large and fleshy, of a purplish-brown color and sweet, agreeable taste. Those produced in Calabria are similar. The *Smyrna raisins* are also large, but of a yellowish-brown color, slightly musky odor, and less agreeable flavor. They are originally brought from the coast of Syria. The *Corinthian raisins,* or *currants* as they are commonly called in this country, are small, bluish black, of a fatty appearance, with a vinous odor and a sweet, slightly tartish taste. Their name is derived from the city in the vicinity of which they were formerly cultivated. At present they are procured chiefly from Zante, Cephalonia, and the other Ionian Islands. In the older Pharmacopœias they are distinguished by the title of *uvæ passæ minores*. Within recent years the production of raisins in California has become an industry of the highest importance. These raisins are coming into large use in the United States and are rapidly replacing those obtained from Malaga; the importation of the latter decreased in the years between 1876 and 1900 at least 90 per cent. The ripe grapes are cut from the vines, spread out on a clay floor, and dried by exposure to the heat of the sun. The drying process usually requires about ten days' time. Artificial heat is used to dry them in rainy weather; sometimes the grapes are partially dried

on the vines; this is done by cutting the stalks of the ripe grapes half way through, and allowing the bunches to remain for a few weeks, a portion of the bark of the vine being removed also to facilitate the process. If it is desirable to remove the waxy bloom on the grapes, the bunches are steeped for a short time in weak alkaline solution, washed and then thoroughly dried.

Raisins usually contain more sugar than do recent grapes. This principle, indeed, is often so abundant that it effloresces on the surface or concretes in separate masses within the substance of the raisin. The average composition of the raisin is given as 32.02 per cent. water, 2.42 nitrogenous material, 0.59 fat, 54.56 sugar, 7.48 other nitrogenous organic matter, 1.72 wood fiber, and 1.21 ash. (König, *Nahrungs- und Genussmittel*, 3te Aufl., ii, 815.) The *sugar of grapes* (*glucose*) differs from that of the cane, being less sweet, less soluble in cold water and much less so in alcohol. In these respects it does not differ from artificial glucose, which is now made in enormous quantities and consumed in food products and candies; the artificial product is made by acting on starch with sulphuric acid (see page 517).

The chief medicinal use of raisins is to flavor demulcent beverages. Taken in substance they are gently laxative, but are also difficult of digestion, and, when largely eaten, sometimes produce unpleasant effects, especially in children.

Radish. *Raphanus sativus* L.—The juice of this well known plant has been used by Grumme in the treatment of *cholelithiasis* as an aid in preventing the formation of biliary calculi. His method is as follows:

White or black radishes are peeled, crushed in a suitable apparatus and the juice expressed. If the treatment is begun during or after an attack, the patient is made to drink on the first day half a cupful (100 mils) (or three and a half fluidounces) of the juice, then a whole cupful and later two cups (400 mils) (or fourteen fluidounces) daily. This amount is taken daily for two or three weeks, whereupon the dose is gradually decreased, until half a cupful is taken three times a week. This treatment is continued for six to eight weeks. When it is repeated, one cupful of juice is taken daily in the beginning, then half a cupful daily and later half a cupful every second day.

Saki reports the presence of an amylolytic enzyme in radish juice. (*J. P. C.*, 1906, 561.)

Sacher recommends the coloring matter from red radishes as a sensitive indicator in alkalimetry; the fresh peels are treated with alcohol and the solution is turned red with acids and green by alkalies.

Randia. *Randia dumetorum* Lam. (Fam. *Rubiaceæ*.)—The fruit of this East India shrub is used by the natives as a fish poison, and is said to act in man as an irritating emetic. According to the *Pharmacographia Indica*, each fruit contains about four grains (0.26 Gm.) of saponin, besides valeric acid. The tincture has been used by James Sawyer (*L. L.*, 1891) as an antispasmodic.

Ranunculus. *Crowfoot. Renoncule*, Fr. *Hahnenfuss*, G.—Most of the plants belonging to the genus *Ranunculus* have similar acrid properties, and, from their close resemblance, are confounded under the common name of *buttercup*. *R. bulbosus* L. was formerly in the Secondary List of the U. S. Pharmacopœia; but *R. sceleratus* L. had attracted more attention in Europe, and *R. acris* L. and *R. flammula* L. were recognized by the Dublin College. In all these species the plant itself is a violent irritant, producing when chewed excessive inflammation in the mouth and throat, and, when swallowed toxic gastritis which may be fatal. The acrid principle appears to be volatile; according to Bigelow, it is yielded to water in distillation. Clarus discovered, in *R. sceleratus* L., besides the acrid volatile oil, a nearly inert resin, and a narcotic principle called *anemonin* or *anemone camphor*, $C_{15}H_{12}O_6$. The volatile oil is soluble in ether, and is decomposed, on standing, into a white amorphous substance having acid properties (*anemonic acid*), $C_{15}H_{14}O_7$, and into anemonin. (*Brit. and For. Med.-Chir. Rev.*, 1859, 181.) Rochebrune states that he has separated from *R. aquatilis* L., *R. flammula L.*, *R. sceleratus* L. and *R. bulbosus* L., crystalline alkaloids to which he has given the name of *ranunculine*, although their identity is doubtful. These alkaloids are violent irritants and active cardiac poisons. (*Toxicolog. Africaine*, i.) Before the introduction of cantharides the green buttercup plants were much employed as vesicants.

Realgar. As_2S_2. *Red Orpiment.*—This is *arsenic disulphide*. It is found native in Saxony, Bohemia, Transylvania, and in various volcanic regions. *Realgar* is artificially made by melting arsenic trioxide with about half its weight of sulphur. Thus prepared, it is of a crystalline texture, of a beautiful ruby-red color, of a uniform conchoidal fracture, somewhat transparent in thin layers, and capable of being sublimed without change. Native realgar is said to be innocuous when taken internally, while that artificially prepared is poisonous, in consequence, according to Guibourt, of containing a little free arsenic trioxide. Realgar is used only as a pigment.

Red Chalk. *Reddle.*—A mineral substance of a deep red color, of a compact texture, dry to the touch, adhering to the tongue, about as hard as chalk, soiling the fingers when handled, and leaving a lively red trace when drawn over paper. It consists of clay and ferric oxide, and is intermediate between *bole* and *red ochre*, containing more ferric oxide than the former and less than the latter. It is used for drawing lines upon wood, etc., and is sometimes made into crayons by levigating and elutriating it, then forming it into a paste with mucilage of gum arabic, molding this into cylinders, and drying it in the shade. It has been used internally as an absorbent and astringent.

Regianin.—This is a principle obtained by Phipson from the nut of *Juglans regia*. It occurs in octahedral, prismatic, or feathery crystals, and gives with ammonia and other alkalies a reddish-purple solution, from which hydrochloric acid precipitates an amorphous powder, *regianic acid*. It is probably identical with the *nucin* obtained from green walnut shells.

Rennet. *Gastric Juice. Liquor Seriparus. Laabessenz*, G.—For a full account of the constitution of gastric juice and its properties the reader is referred to works upon physiology. The crude juice was applied by P. S. Physick to foul ulcers. *Rennet* is an aqueous or vinous infusion of the dried stomach of the calf, though that of the sheep or other animal would probably answer the same purpose. It is much used, as every one knows, for curdling milk, a property which it owes to a portion of the gastric secretion, retained and dried in the mucous tissue of the stomach. Whether the milk-curdling ferment is identical with the proteolytic ferment (pepsin)

is not yet definitely determined. George Ellis prepared *rennet wine* as follows: Take the stomach of a calf immediately after the animal has been killed, cut off and reject about three inches of the upper or cardiac portion, slit the stomach longitudinally, wipe it gently with a dry napkin so as to remove as little of the clean mucus as possible, then cut it into small pieces, the smaller the better, put it into a common wine bottle, fill the bottle with good sherry, and let it stand corked for three weeks. It is known to be good if a teaspoonful will coagulate half a pint of milk in two minutes at 37.7° C. (100° F.). The *dose* is a teaspoonful in a wineglassful of water, immediately after each meal. [See next article.)

Rennin. *Renninum. N. F. IV.*—Under this name the National Formulary IV has introduced in solid form, the milk-curdling principles from calves' stomachs. It possesses several advantages over liquid rennet and it is believed to retain its powers longer than the liquid form. It is described as follows:

"The partially purified milk-curdling enzyme obtained from the glandular layer of the stomach of the calf, *Bos taurus* Linné (Fam. *Bovidæ*), and capable of coagulating not less than 25,000 times its weight of fresh milk. Rennin of a higher coagulating power may be brought to the standard by admixture with sodium chloride and sugar of milk. Rennin deteriorates rapidly and must be kept in well-stoppered, amber-colored bottles, and stored in a cool place." *N. F. IV.*

"Rennin occurs as a grayish-white or yellowish-white powder, or as pale yellow grains or scales having a characteristic and slightly saline taste and a peculiar, not unpleasant odor. It is slightly hygroscopic.

"It is slowly soluble in water and in diluted alcohol, the solutions being more or less opalescent.

"When mounted in water or diluted alcohol and examined microscopically, it shows no cellular structure, and no blue coloration is produced on the addition of iodine T.S.

"*Assay.*—Mix 0.1 Gm. of Rennin with 50 mils of distilled water by stirring (vigorous shaking or violent agitation of this liquid must be avoided) and allow the liquid to stand for exactly fifteen minutes. Place 50 mils of cow's milk in a beaker about 12 cm. in height and 5 cm. in width, warm rapidly on a water bath to 43° C., add 1 mil of the Rennin solution and stir the mixture slowly for ten seconds. Maintain the temperature of the bath at 43° C. for ten minutes after the addition of the Rennin solution, remove the beaker from the bath and tip it to an angle of 45 degrees. The milk must have lost its fluidity to the extent of exhibiting a decidedly convex surface. An additional thirty seconds on the water bath produces a firm curd." *N. F. IV.*

Rennin was admitted to the National Formulary IV for the purpose of using it as an ingredient in making Compound Elixir of Pepsin and Rennin.

Resaldol. *Resorcin benzoyl carbonic acid ethyl ester (2,4-dioxybenzoyl-o-benzoic acid ethyl ester).* $C_{20}H_{14}O_5(CH_3CO)_2$.—*Resaldol* is made by acetylating the product of the reaction between chlormethyl-salicylic aldehyde and resorcinol. It is an amorphous yellowish-brown powder of an astringent taste, insoluble in water and dilute acids, but soluble in alkalies. According to Impens (*D. M. W.*, 1913, p. 1827), it acts much like cotoin (see p. 1344), over which it has the advantages of being tasteless and non-irritant. It is used in *tuberculous* and other forms of *enteritis.* The *dose* is eight grains (0.5 Gm.) several times a day.

Resalgin. *Antipyrine Resorcylate.* $(C_{11}H_{12}N_2O_2)_2.C_7H_6O_4$.—This occurs in crystalline needles soluble in 150 parts of cold water and 20 parts of boiling water, readily soluble in alcohol, ether, and chloroform. It is obtained by acting on antipyrine with potassium resorcylate. Forms colorless, odorless crystals melting at 110.5° C. (231° F.).

Betaresalgin, also called *resorcylalgin,* is obtained from betaresorcylic acid and antipyrine. It forms shiny white to pinkish crystals. It is soluble in alcohol, ether and chloroform and in 150 parts water. Melting point 115° C. (239° F.). It exercises both an antipyretic and an anodyne action.

Reseda. *Reseda Luteola* L. *Weld. Dyer's Weed. Herbe Jaune, Gaude,* Fr. *Wau, Gelbkraut, Harnkraut,* G. (Fam. *Resedaceæ.*)—An annual European plant, naturalized on roadsides and ballast from Massachusetts to Pennsylvania. The plant grows to a height of 6 dm., possesses alternate lanceolate leaves and small greenish-yellow flowers. It is inodorous, and has a bitter taste, which is very persistent. Volhard showed that allyl thiocyanate, $C_3H_5.SCN$ (volatile oil of mustard), was present in the root, and Chevreul obtained from it by sublimation a peculiar yellow coloring matter, which he called *luteolin.* Hlasiwetz and Pfaundler (1895) assign to it the formula $C_{15}H_{10}O_62H_2O$ and find it to be tetrahydroxyflavone. This forms yellow crystals of silky luster, insoluble in water, soluble in alcohol. It dissolves in alkalies with deep yellow color. It is used especially in silk dyeing. A. G. Perkin (*J. Chem. S.*, 1896) investigated the salts of luteolin, and called attention to the similarity of its properties to those of *fisetin.* In medicine it has been employed as a diaphoretic and diuretic, but it is now used only for dyeing purposes.

Resineon.—This is a volatile oil obtained from black tar oil by distillation and stated to be free of phenol. It boils at 148° C. (298.4° F.) and is used externally as a dressing for wounds and injuries and as an antiseptic in *skin affections.* A 1 to 8 ointment is applied by inunction in *chronic eczema.*

Resol.—A proprietary disinfectant said to be made by saponifying wood tar with potassium hydroxide and adding wood spirit.

Resopyrine. $C_{11}H_{12}N_2O + C_6H_4(OH)_2$.—Made by mixing solutions of 30 parts of antipyrine and 11 parts of resorcinol. A crystalline mass separates which should be recrystallized from alcohol. It is insoluble in water.

Resorbin.—An ointment vehicle made by emulsifying almond oil and water by means of a little yellow wax, gelatin, and soap, to which is added some lanolin. It is asserted that it greatly facilitates the absorption of medicaments.

Resorcinal.—*Resorcinal* is obtained by fusing equal parts of resorcinol and iodoform. It is a brown powder of iodine-like odor and used as a vulnerary and dermatic, as 20 per cent. dusting powder, or a 5 to 10 per cent. ointment.

Retamine. $C_{15}H_{26}N_2O$.—This is an alkaloid, crystallizing in long needles, melting at 162° C. (323.6° F.), with decomposition, which has been isolated by Battandier and Malosse from the young shoots and branches of *Retama sphærocarpa* Raf. (*Cytisus sphærocarpus* O. Kze.).

Retinol. *Codoil. Rosinol. Rosin Oil.* $C_{32}H_{16}$.—A product obtained by the distillation of rosin. It

forms a yellowish oil boiling at temperatures over 280° C. (536° F.). It is stated that *retinol* does not irritate the skin, is unaltered by light, is mildly antiseptic, does not become rancid, and is very inexpensive; qualities which, taken along with its extraordinary solvent power, bid fair to make it a valuable vehicle for ointments. Among the substances dissolved by it are: salol, 1–10; iodol, 1–50; naphthol, 1–50; thymol iodide, 1–50; camphor, 1–20; chrysophanic acid, 1–40; cocaine, 1–30; codeine, 1–40; and strychnine, 1–40. It is miscible in all proportions with oil of juniper, phenol, turpentine, alcohol, and ether. Resorcinol, if dissolved in glycerin, may be mixed with retinol, and so may iodoform if it be dissolved in a little ether. Iodol is dissolved, but soon precipitates as a resinous mass. Phosphorus is also dissolved, and the solution remains unchanged indefinitely. Retinol mixes readily with fats, oils, vaseline, lard, lanolin, glycerin, cacao butter, etc., and may be used in ointments. In cases where a liquid is not undesirable, retinol, owing to its antiseptic properties, can with great advantage replace these bodies. Upon the mucous membrane retinol seems to act as a mild stimulant antiseptic; it has been used with alleged excellent results locally in *otitis*, *vaginitis*, *rhinitis*, and other mucous diseases. Injections of it in *gonorrhea* are said to be remarkably effective. As a means of administering phosphorus it is especially recommended.

Rexotan.—This is a condensation product of tannin, urea and formaldehyde. It is in the form of a yellowish-brown powder, without odor or taste, insoluble in most of the ordinary solvents or in acid liquids, but decomposed by alkalies with the liberation of formaldehyde.

The advantage is claimed for this preparation, like many other of the organic compounds of tannin, that it is insoluble in cold water and dilute acids and, therefore, not dissolved in the stomach, but being easily soluble in solutions of the carbonates and phosphates exercises its astringent effect in the intestinal tract and further that in the intestines the formaldehyde is slowly liberated so that the drug exercises both an astringent and antiseptic action. It is used in the treatment of various types of *diarrhea* in *doses* of eight grains (0.5 Gm.) three to four times a day.

Rhamnus Cathartica. *N. F. IV. Buckthorn Berries. Baccæ Spinæ Cervinæ.*—"The dried, ripe fruit of *Rhamnus cathartica* Linné (Fam. *Rhamnaceæ*), without the presence of more than 5 per cent. of the unripe fruit or other foreign matter." *N. F.*

The *R. cathartica* Linn, or common buckthorn, grows in Europe along with *R. Frangula*, and has become naturalized in this country. Its bark is probably often sold for the official Frangula. It is distinguished by its more spreading, thorny habit, and its diœcious flowers, which are thickly clustered in the axils and have their parts in fours. The leaves are more acute, have their margins finely serrate and their lateral veins mostly proceeding from the proximal half of the midrib. The fruit is black.

The berries which are ripened in September, are of the size of a pea, round, somewhat flattened at top, black, smooth, shining, with four seeds in a green, juicy parenchyma. Their odor is unpleasant, their taste bitterish, acrid, and nauseous. Their blackish, expressed juice was formerly recognized in the Br. Ph. under the name of *Rhamni succus*. It is reddened by the acids, and from deep green is rendered light by the alkalies. Upon standing it soon begins to ferment, and becomes red in consequence of the formation of acetic acid. Evaporated to dryness, with the addition of lime or an alkali, it forms the color called by painters *sap-green*. The dried fruit of another species, *R. infectoria*, yields a rich yellow color, and is employed in the arts under the name of *French berries*.

The National Formulary IV describes buckthorn berries as follows:

"Flattened, globoid or ovoid, from 4 to 8 mm. in diameter; externally purplish-black, wrinkled from shrinking of the mesocarp in drying; three- to four-celled, each cell containing a brown, triangular-convex, seed-like nutlet; in the fully dried, ripe fruit the pedicel is usually lacking. Odor faint, unpleasant; taste at first sweetish, then nauseating and bitter; it colors the saliva purplish-red. When macerated in water the drupe readily assumes its original globular shape, about 1 cm. in diameter. The expressed pulp is colored red by acids and greenish-yellow by alkalies. Shake out an aqueous infusion of Rhamnus Cathartica with ether, separate the ethereal solution and shake it with 5 per cent. ammonia water; the ammonia solution assumes a cherry-red color. The unripe fruit, which is to be rejected, is green to greenish-brown, firm, furrowed, pedicel usually attached; very bitter; it colors the saliva greenish-yellow. Rhamnus Cathartica yields not more than 5 per cent. of ash." *N. F.*

The blackish, expressed juice of Buckthorn berries was formerly recognized in the Br. Ph. under the name of *Rhamni Succus*. It has the color, odor, and taste of the parenchyma, is reddened by the acids, and from deep green is rendered light green by the alkalies. Upon standing it soon begins to ferment, and becomes red in consequence of the formation of acetic acid. Evaporated to dryness, with the addition of lime or an alkali, it forms the color called by painters *sap-green*. The dried fruit of another species, *R. infectoria*, yields a yellow color, and is employed in the arts under the name of *French berries*.

Tschirch and Polacco, in 1900, investigated the constituents of buckthorn berries and found certain yellow coloring substances. The researches of N. Waljaschko and N. Krassowski since demonstrated that the fruits of *R. cathartica* contain the same yellow coloring matters as are contained in the fruits of *R. infectoria* and *R. tinctoria*, namely, *quercetin* and *rhamnin*, both existing in *R. cathartica* in the form of glucosides, which are split up by the action of an enzyme contained in the fruits: *Rhamnin*, for example, from the glucoside *xanthorhamnin*. The yellow coloring matters of Tschirch and Polacco, therefore, cannot be regarded as pure substances. They also extended the investigations of the former concerning the purgative substances contained in buckthorn fruits, with results confirming the theory advanced by Tschirch. They found the fruits to contain about 2 per cent. of emodin-substances and as cleavage products of the glucosides obtained by the action of ferments from the emodin-substances: *Emodin*, identical with *frangula emodin* and *rhamnosid;* the *emodin of rhamnoxanthin* ($C_{21}H_{20}O_9 + H_2O$), which is isomeric but not identical with frangulin; *rhamnonigrin*, and a resin like body containing emodin. Other constituents found in buckthorn berries are: fixed

oil, succinic acid, glucose, galactose, rhamnose, and a pentose, but of the four sugars only glucose was present in the free state, the others being derived from the glucosides. (*Ph. Ztg.*, 1909, No. 16, 159.) Tschirch and Bromberger (*Schw. Woch. f. Ch. v. Ph.*, 1912, p. 193) report the following constituents found in a 15 Kilo sample upon which they did considerable work: *Rhamno-sterin*, $C_{18}H_{28}O_2$; *rhamno-fluorin*, $C_{14}H_{12}O_6$; *emodin*, $C_{15}H_{10}O_5$; *iso-emodin*, $C_{15}H_{10}O_5$; *chrysophanol* $(C_{14}H_5O_2)CH_3(OH)_2$. A fluidextract and a syrup of buckthorn berries are contained in the N. F. (see Part III).

The *dose* of the dried berries is from ten to twenty grains (0.65–1.2 Gm.). Among other species of Rhamnus which have claimed attention are *R. Wightii*, W. & A., a common shrub of Madras and Bombay (*P. J.*, Feb., 1888), and *R. californica*, Eschsch. (*R. humboldtiana*, Roem. and Schult.), of Mexico, which S. E. Sosa states sometimes produces paralysis in children (*El Estudio*, 1890). (See also *Cascara Sagrada.*)

Rhigolene.—This name was given by H. J. Bigelow of Boston, to a very light, inflammable liquid, obtained by distilling petroleum, and separating the liquids of the lowest boiling point by redistillation, until one is obtained which boils at about 18° C. (64.4° F.). A degree of cold –9° C. (15.8° F.) is, according to Bigelow, obtained through the evaporation of this liquid by means of the common atomizer or "spray-producer." This is the chief use of the liquid, which may be employed in producing congelation of any part of the body preparatory to a surgical operation, or a great degree of cold for any other purpose. It should, when not in use, be kept in a cool place, in bottles tightly corked, or otherwise it will be rapidly evaporated. In a warm place it might break the bottles through its extreme volatility, unless the stopper should previously be driven out. The vapor is inflammable and care should be exercised in using it near a flame.

Rhizophora Mangle.—The red bark of the South American *mangrove tree* has been used for many years by the natives as a febrifuge but more recently Duque and Moreno (*S. M.*, 1905, p. 479) have claimed that it is a specific in *leprosy*. They administer a beginning *dose* of one fluidrachm (3.75 mils) of the fluidextract twice a day which is gradually increased until the patient is taking a fluidounce and a half (45 mils) daily.

Rhododendron. *Rhododendron Chrysanthemum* Pall. *Yellow-flowered Rhododendron. Rosebay. Snowrose. Rosage*, Fr. *Alpenrose, Schneerose, Gichtrose*, G. (Fam. *Ericaceæ.*)—The leaves of this rhododendron have long been employed in Siberia as a remedy in *rheumatism*, and to a less extent in *gout* and *syphilis*. They yield their virtue to water and alcohol, and, according to von Archangelski, contain three proximate principles; *rhododendrol*, $C_{10}H_{12}O_2$; *rhododendrin*, $C_{16}H_{22}O_7$; and a glucoside resembling digitalin and very toxic. The *dose* of the dried leaves is said to be two drachms (7.7 Gm.), given in infusion.

G. F. Kuehnel found in leaves of the "great laurel," *Rhododendron maximum* L., a common shrub in the Alleghenies from New York to Georgia, *arbutin*, *ericolin*, and *ursone*. (*A. J. P.*, 1885.)

Rhus.—The genus *Rhus* contains various species which have the property—probably even without direct contact—of so violently irritating susceptible skins as to produce severe dermatitis. Of these poisonous species there are six which are indigenous to the United States.

R. vernix L. (*R. venenata* DC.)—*Swamp Sumac, Poison Sumach, Poison Elder* is our most poisonous species. It is a handsome shrub or small tree, usually ten or fifteen feet high. The bark of the trunk is dark gray, of the branches lighter, of the extreme twigs and petioles pale to deep red. The leaves are pinnate, with three to six pairs of opposite leaflets, and an odd terminal one. These are oblong or oval, entire or slightly sinuate, acuminate, smooth, and, except the one at the end, nearly sessile. The flowers are polygamous, very small, greenish, and in loose or slender axillary panicles. The berries are small, roundish, and greenish white. The tree grows in swamps and low grounds from Canada to Carolina, and flowers in June and July. It was confounded by the older botanists with *R. vernicifera* DC., of Japan, the Japanese lacquer tree, which has similar poisonous properties. Its activity is said to depend upon *urushic acid.*

Rhus Michauxii Sargent (*R. pumila* Michx.) is a rare Southern species, growing in upper Carolina and Georgia, and not more than a foot in height. It is characterized by its pubescent branches and petioles, by its pinnate leaves, with many pairs of oval, nearly acuminate, incised-dentate leaflets, downy beneath, and by its silky fruit. According to Pursh, it is the most poisonous of the genus.

Rhus diversiloba Torrey and Gray (*R. lobata* Hooker) is found on our Pacific border. It is there generally known as *Poison Oak*, and closely resembles the common poison ivy or poison oak. (*R. Toxicodendron* L.)

Rhus Metopium L. (*Metopium Linnæa*, Engelm.), *Mountain Manchineel, Coral Sumac*, is a West Indian species, growing also in the "hummock" lands of Southern Florida. It is a small tree, the bark, when wounded, exuding a gum-resin (*hog gum*) to which medicinal properties are ascribed. The leaves are pinnate with fine leaflets. To the acid red fruit is due the name Coral Sumac. It is exceedingly poisonous.

Rhus Toxicodendron (*R. radicans* L.), *Poison Oak, Poison Ivy*, whose fresh leaves were formerly official in the U. S. Pharmacopœia under the name of *Rhus Toxicodendron*, U. S., 1890, is a woody vine climbing by numerous aerial rootlets to considerable heights and showing considerable variation. The leaves are 3-foliate, the leaflets being ovate or rhombic, 2.5 to 15 cm. long, entire or sparingly dentate or sinuate, acute or short-acuminate, the lateral sessile or short-stalked, are inequilateral, the terminal ones stalked. The flowers are green, 3 mm. broad, in loose axillary panicles, 2 to 8 cm. long; the fruit globose-oblong, whitish or cream colored, resembling that of *R. Vernix.*

The milky juice, of the poisonous species of *Rhus*, becomes black on exposure to the air, and leaves upon linen or other cloth a stain, which cannot afterwards be removed by washing with soap and water, or by alcohol either hot or cold, but deepens by age. It has been proposed as an indelible ink. Ether dissolves it; applied to the skin it frequently causes inflammation and vesication.

While there is a fairly general agreement that the toxic constituent of the poisonous species of Rhus is a non-volatile substance, there is much evidence that there is a volatile poison also in this plant. (Bessey, *A. J. P.*, 1914, p. 112.) Several authors are inclined to explain the poisoning which

results to sensitive persons who pass near Rhus plants without touching them, by saying that the poison resides in the pollen and the plant hairs. The latter may be carried by air currents or may be transported on clothes, or tools, or animals, which after brushing against the plant are able to transfer the poison to susceptible persons. Warren (*A. J. P.*, 1913, p. 548) was unable to detect a poisonous principle in the pollen grains of *Rhus Vernix*. See also Tschirch and Stevens, *A. J. P.*, 1906, p. 63. Besides the unidentifiable poisonous principle of rhus there is present an iron greening tannin, chlorophyll, wax, fixed oil, resin, sugar, albumen, pectin, gum, starch, and oxalic acid.

The poisonous rhus when taken internally appears to be possessed of narcotic besides irritant properties, vomiting, drowsiness, stupor, dilated pupils, convulsive movements, delirium, and fever having been present in poisoning by them. (*Am. J. M. S.*, April, 1866; also *M. Rep.*, Nov., 1867.) The tincture of rhus has been used especially by homeopathic practitioners in the treatment of *subacute* and *chronic rheumatism*, and the practice has found imitation.

Some years ago H. C. Wood made extended trials of the remedy, using a homeopathic tincture obtained from a homeopathic pharmacy, in various doses (homeopathic, small, and large), upon a large number of cases of *subacute, chronic*, and *acute rheumatism*, in the Philadelphia Hospital, but he was not able to perceive that the patients progressed more rapidly when taking it than when they were simply nursed. The best preparation would undoubtedly be a concentrated alcoholic tincture, made from the green drug; strength of one to four. The *dose*, of a 25 per cent. tincture given by H. C. Wood was from one to five minims (0.06–0.3 mil), three times a day. The solid extract is an ineligible preparation, owing to the extreme volatility of the active principle of the crude drug.

Rhus canadensis Marsh. (*R. aromatica* Ait) (Fam. *Anacardiaceæ*).—This indigenous plant, growing in dry soil from Maine and Southern Ontario to Florida and westward, has been highly recommended in the treatment of *nocturnal incontinence* of urine by a number of clinicians of repute. (See *G. H. M. C.*, 1889; also *Annals of Gynæc.*, 1890.) For elaborate description of the bark, see *Newer Materia Medica*. The adult *dose* is twenty or thirty minims (1.3–1.8 mils) of the fluidextract of the bark, three times a day, given in aromatized solution.

Rhus Glabra. *N. F. IV* (*U. S. VIII*). *Rhus Glabrum. U. S.* 1870. *Sumac Berries. Sleek. Scarlet. White Sumach. Shoe-make. Vinegar Tree. Sumac*, Fr. *Sumach*, G.—"The dried, ripe fruit of *Rhus glabra* Linné (Fam. *Anacardiaceæ*), without the presence of more than 5 per cent. of stems or other foreign matter." *N. F.*

Rhus glabra called variously *smooth sumach, Pennsylvania sumach*, and *upland sumach*, is an indigenous shrub from four to twelve feet or more in height. The leaves are upon smooth petioles, and consist of numerous opposite leaflets, with an odd one at the extremity, all of which are lanceolate, acuminate, acutely serrate, glabrous, green on their upper surface, and whitish beneath. In the autumn their color changes to a beautiful red. The flowers are greenish red, and disposed in large, erect, terminal compound thryses. The fruit is in clusters of small crimson berries.

The shrub is found in Canada and almost all parts of the United States, growing in old neglected fields, along fences, and on the borders of woods. The flowers appear in July, and the fruit ripens in the early part of autumn. The bark and leaves are astringent, and are largely used, especially the leaves, in tanning leather and in dyeing. The sumach for the manufacture of extract for tanners' use is largely cultivated in Virginia, where the annual crop reaches from 7000 to 8000 tons, and is collected at any time between the first of July and the appearance of frost.

The berries have a sour, astringent, not unpleasant taste, and are often eaten by the country people with impunity. They are described in the National Formulary IV as follows:

"Nearly globular, ovoid, more or less reniform, somewhat compressed, about 5 mm. in length and 2 mm. in diameter; externally dark red, velvety with short hairs, summit with remains of the short style, base occasionally with the five-cleft calyx and a short pedicel; endocarp, smooth, shiny, light red; one-celled, one-seeded; seeds dark brown, smooth. Inodorous; taste acidulous and slightly astringent. The powder is brownish-red, and, when examined under the microscope, exhibits irregular fragments; non-glandular hairs, more or less elliptical or ovoid or spatulate, about 0.15 mm. in length and from 0.045 to 0.08 mm. in width, filled with a pink or red cell sap in which occasionally occur rod-shaped crystals; glandular hairs with a short one-celled stalk and multicellular head, from 0.045 to 0.075 mm. in length; fragments of endosperm numerous; fragments of endocarp showing very small stone cells with irregularly thickened walls, readily determined by the use of aniline sulphate T.S. and sulphuric acid; fragments of embryo with rather small cells containing a fixed oil; occasional reddish colored fragments of epidermis and underlying spiral tracheæ of the mesocarp. Mix 1 Gm. of powdered Rhus Glabra with 10 mils of hot water, shake the mixture occasionally until cold, filter, and allow the filtrate to evaporate spontaneously in a watch crystal; numerous, feather-shaped crystals separate which polarize light strongly with a distinct play of colors. Rhus Glabra yields not more than 4 per cent. of ash." *N. F.*

W. J. Watson ascertained that free malic acid and acid calcium malate coexist in the berries, which contain also, upon the same authority, tannic and gallic acids, fixed oil, extractive, red coloring matter, and a little volatile oil. (*A. J. P.*, xxv, 194). A medicinal wine has been prepared from the fruit. (*M. S. R.*, Feb. 9, 1867.) For a paper on the relative proportion of the constituents found in the husk and seed portion of the fruit by Frankforter and Martin, see *A. J. P.*, 1904, 151.

Excrescences are produced under the leaves resembling Chinese galls in character, and containing large quantities of tannic and gallic acids. These have been used as a substitute for the imported galls by Walters of New York, who thought them in every respect preferable. They may be collected at little expense, as they are produced very abundantly, especially in the Western States.

Henry Trimble collected some galls from the leaves of *R. glabra* and found that they contained 61.70 per cent. of tannin, reckoned on the weight of the air-dried galls, or 70.90 per cent. of the weight of absolutely dry material. (*A. J. P.*, 1890, p. 564.)

From the experiments of Stenhouse (*A. J. P.*, xxxiv, 252), it appears that the tannic acid of

sumach is identical with that of galls, being, like it, resolved, under the influence of sulphuric acid, into glucose and gallic acid, and this change is supposed to take place spontaneously in sumach when long kept.

The percentage of tannin in Virginia sumach rises at times as high as 27 per cent., but falls a few per cent. below this as the season advances. Samples of leaves gathered along the Mississippi near Dubuque, Iowa, in July and August, yielded 16.36 per cent. and 15.75 per cent. respectively. (*A. J. P.*, 1888, p. 389.) The proportion of tannic acid in the European sumach falls from 6 to 8 per cent. below the percentage of the Virginia sumach, yet the European is much preferred by tanners and dyers. By using Sicilian sumach it is possible to make the finer white leathers so much used for gloves and fancy shoes, while by the employment of the American product the leather has a yellow color, apparently due to a coloring matter, which, according to Loewe, consists of quercitrin and quercitin, and exists in larger quantity in the American than in the Sicilian drug. Enormous quantities of a dark-red, semi-fluid, bitter, astringent extract are prepared in Virginia from sumach, and used both in America and in Europe. It is said to contain from 25 to 30 per cent. of tannin.

Recently the fruits of *Rhus glabra* have been replaced by those of the *Stag Horn Sumac* (*Rhus typhina* L.) This shrub is very abundant in the eastern United States. The fruits resemble those of rhus glabra both in form and size but are distinguished by being covered with needle-like crimson hairs which are frequently over 2 mm. long. For detailed description of the fruits of these two plants see Kraemer. (*A. J. P.*, 1913, p. 398.)

Sumach berries are astringent and refrigerant. A strong decoction, or the fluidextract diluted, affords a very effective and pleasant gargle in *angina*, especially in combination with potassium chlorate. *Fluidextractum Rhois Glabræ* was official in the U. S. VIII, but then deleted. It was admitted to the National Formulary IV with a slight alteration in the menstruum. The fluidextract affords an excellent astringent in relaxing *diarrheas* and other conditions where the tannin drugs are useful. The *dose* of the fluidextract is fifteen to thirty minims (1–2 mils).

Ricin is the name given by Kobert and Stillmark to the toxic constituent of castor beans (*Ricinus communis*). It belongs to the class of albuminoids and is of the character of an enzyme. It is a white powder which forms a turbid liquid in a 1 per cent. solution of sodium chloride. It has been proposed by Jacoby to detect the presence of pepsin in liquids by using *ricin*. (*M. R.*, 1907.) For a valuable paper by Finnemore and Deane read before the British Pharmaceutical Conference, 1905, see *M. R.*, 1906, 165. The toxic symptoms, which frequently do not come on for several hours after the ingestion of the poison, are due primarily to the intensely irritant action of the substance, and consist of diarrhea, with suppression of the urine, and frequently jaundice, probably from irritation of the mucous membrane of the biliary ducts. Müller (*A. E. P. P.*, 1899, xlii) states that the poison also has a direct action upon the medulla, leading to the fall of blood pressure and lessened respiratory activity.

The effects of ricin in many directions bear a striking resemblance to the effects of bacterial toxins. Thus, for example, it produces a leucocytosis and an agglutination of the red corpuscles. The most interesting, however, of these resemblances is the production of immunity and the formation of antitoxic substances.

Rimu Resin.—The resin of the *Dacrydium cupressinum* Solander, the New Zealand red pine or *rimu*, a large coniferous tree of New Zealand, is characterized by its rose color and its crystalline appearance. It is composed chiefly of a crystalline acid resin, *rimuic acid*. (*Chem. News*, lxxxviii, 20.)

Robinia. *Robinia Pseudo-Acacia* L. *Locust Tree. False Acacia. Robinier*, Fr. *Falsche Akasie*, G. (*Fam. Leguminosæ.*)—This well-known indigenous tree has a place in the materia medica of the eclectics. The bark of the root is the most active part, and is said to be tonic, and in large doses purgative and emetic. The root and inner bark are poisonous to cattle. The leaves, on the other hand, are said to offer a wholesome food for foraging animals. This would seem confirmed by the experiment of Paven, who failed to find in them any poisonous principles. (For an elaborate investigation of its histology, see *P. J.*, 67, 153.) F. B. Power and J. Cambier (*Ph. Rund.*, Feb., 1890) found an alkaloid identical with *choline;* also globulin and a phytalbumose, which produces purging and vomiting. It is precipitated by alkaloidal reagents. The bark also contains a poisonous albuminoid or enzyme, *robinalbin*, which, according to Kobert (*M. Bull.*, April, 1891), is similar to, but not identical with, ricin. Power (*P. J.*, Aug. 17, 1901) summarizes the results of a more detailed investigation of this bark. He names the poisonous proteid *robin* and states that it belongs to the class of nucleo-proteids. He finds evidences of one or more alkaloids; by hydrolysis he obtained *syringic acid*, $C_9H_{10}O_5$, and a red amorphous substance, *syringenin*. These products indicate the glucoside *syringin*, $C_{17}H_{24}O_9$. He also considers that *gluco-syringic acid*, $C_{15}H_{20}O_{10}$, may pre-exist in the bark. Power subsequently reaffirmed the presence of the protein, robin, in robinia bark, and confirms its toxic properties and enzymic action. (*A. J. P.*, 1913, 339.) Robin has emetic and purgative properties. Three cases of the poisoning of children by the root have been recorded. (*Ann. Thér.*, 1860, 64.) Z. T. Emery (*N. Y. M. J.*, Jan. 22, 1887) reports the poisoning of thirty-two boys from chewing the inner bark of the tree. The symptoms in the mildest cases were vomiting and flushed face, dryness of the throat and mouth, and dilated pupils. In the severest cases, to these were added epigastric pain, extremely feeble, intermittent heart action, and stupor.

Robinia Nicou Aubl., now known as *Lonchocapus Rufescens* Benth.—According to the researches of Geoffroy (*Annal. de l'Inst. botanico-geologique colon. de Marseille*, 1895), this leguminous plant, which is used in Guiana for the purpose of stupefying fish, contains an active principle, *nicoline* (C_3H_4O), which crystallizes in oblique, rhomboidal tables. It has been found by E. Boinet (*C. R. S. B.*, 1896, 10 s., iii) to produce in the lower animals a short primary stage of excitation, followed by one of stupor, great muscular relaxation, enfeeblement of sensibility, mydriasis, fall of temperature, cyanosis, and death through centric paralysis of the respiration, though there is also fall of arterial pressure. In the dog there was salivation and vomiting.

Rosa.—Of the genus *rosa* at least four species

have been, and probably to some extent are still, use in medicine—namely, *Rosa canina* L., *Rosa centifolia* L., *Rosa damascena* Mill., and *Rosa gallica* L.

Rosa canina.—The *Dog Rose, Wild Brier,* or *Hip Tree,* of Europe, is distinguished by its prickly stem and petioles, and ovate, smooth, rigid leaves. It has white or pale red flowers, having usually five obcordate fragrant petals. The fruit consists of a fleshy, hollow receptacle, bearing on its inner surface a number of hairy achenes. The ripe fruit, which is usually employed in the fresh condition, is ovoid, smooth, shiny and of a reddish color. The summit is crowned with 5-calyx teeth. Rose hips possess a pleasant, sweet, acidulous taste. It was formerly official in the British Pharmacopœia under the name of *Rosæ Caninæ Fructus.* It contains about 30 per cent. of sugar, combined with citric and malic acids, also salts of these acids, and a trace of tannin. It was used for the preparation of an acidulous confection. Vanillin has also been found present in the petals.

Rosa centifolia has prickly stems and the leaves consist of two or three pairs of leaflets, with an odd one at the summit, closely attached to the common footstalk, which is rough, but without spines. The leaflets are ovate, broad, serrate, pointed, and hairy on the under surface. The flowers are large, with many petals, generally of a pale red color, and supported upon peduncles beset with short bristly hairs. The varieties of *R. centifolia,* produced by its almost universal cultivation, are very numerous, but the plant is said to grow with single flowers in the eastern part of the Caucasus. It is very closely allied to *R. gallica,* some botanists maintaining that the species are really one. The petals, which were recognized by the U. S. P., 1890, as *pale rose,* are roundish-obovate and retuse, or obcordate, pink, fragrant, sweetish, slightly bitter, and faintly astringent. They contain volatile oil, malic and tartaric acids, tannin, fat, resin, sugar, and a coloring matter which seems to be identical with that of the red rose. They should be collected when the flower is fully expanded but has not begun to fall. Their fragrance is impaired but not lost by drying. They may be preserved for a considerable time by compressing them with alternate layers of common salt in a well-closed vessel, or beating them with twice their weight of that substance. A rose water is often prepared from them by distillation.

Rosa damascena is not known in the wild state, and is thought by some botanists to have been produced by cultivation by hybridizing *R. gallica* with *R. canina.* It is the rose which is cultivated in Turkey and yields the commercial *otto of rose.* (See *Oleum Rosæ,* p. 870.) It is a tall shrub with semi-double, light red to white flowers of moderate size, having several on a branch, though not clustered. Its volatile oil is the base of rose water.

Rosemary. *Rosmarinus. Folia Rosmarini, s. Roris Marini. Folia Anthos. Feuilles de Romarin,* Fr. Cod. *Rosmarin, Rosmarinblätter,* G. *Rosmarino,* It. *Romero,* Sp.—"The leaves of *Rosmarinus officinalis* (Fam. *Labiatæ*)." *U. S.,* 1880. *Rosmary* is a small evergreen shrub, with an erect stem, divided into many long, slender, ash-colored branches. The leaves are numerous, sessile, opposite, about 2.5 cm. long, rigid, linear, entire, obtuse at the summit, folded backward at the edges, of a firm consistence, smooth and green on the upper surface, whitish, woolly, and glandular beneath. The flowers are axillary, pale blue or white. The plant grows spontaneously in the countries which border on the Mediterranean, and is cultivated in the gardens of Europe and this country. The leaves, which have already been described, have a strong balsamic odor, which is possessed, but in a less degree, by all parts of the plant. Their taste is bitter and camphorous. These properties are imparted partially to water, completely to alcohol, and depend on the volatile oil. (See *Oleum Rosmarini,* p. 787.) The tops lose a portion of their sensible properties by drying, and become inodorous by age. Rosemary is gently stimulant, and has been considered emmenagogue. In the practice of this country it is scarcely used; but in Europe, especially on the continent, it enters into the composition of several syrups, tinctures, etc., to which it imparts its agreeable odor and excitant property. It is sometimes added to sternutatory powders, and is used externally in connection with other aromatics in the form of fomentation. In some countries it is employed as a condiment; and its flowers, which are much sought after by the bees, impart their peculiar flavor to the honey of the districts in which the plant abounds.

Rotten Stone. *Terra Cariosa.*—An earthy mineral, occurring in light, dull, friable masses, dry to the touch, of a very fine grain, and of an ash-brown color. It is obtained from Derbyshire, in England, and is used for polishing metals. For a particular account of it, see *A. J. P.,* 1860, 463.

Rourea. *Rourea oblongifolia* Hook. and Arn. (Fam. *Connaraceæ.*)—This Mexican creeper is affirmed to contain an alkaloid, and to act as a violent convulsant poison. (*El Estudio,* 1890.)

Rubia. *Garance,* Fr. *Krappwurzel, Färberröthe,* G. *Robbia,* It. *Rubia de tintoreros, Granza,* Sp.—Under this name the U. S. P. formerly recognized *madder, Rubia tinctorum* L. (Fam. *Rubiaceæ.*) The root of *dyer's madder* is perennial, and consists of numerous long, succulent fibers, varying in thickness from the size of a quill to that of the little finger, and uniting at the top in a common head, from which also proceed side-roots that run near the surface of the ground, and send up many annual stems. The quadrangular stems are furnished with short prickles by which they adhere to neighboring plants, upon which they climb. The leaves are arranged in whorls at the joints of the stem. The flowers are small, yellow and terminal. The plant is a native of Southern Europe. The root, which is dug up the third summer, enters commerce either in the form of the whole root deprived of its cuticle, or in the form of a reddish-brown powder. Madder has a weak, peculiar odor, and a bitterish, astringent taste, and imparts these properties, as well as a red color, to water and alcohol. It contains as its most important constituent *alizarin,* $C_{14}H_6(OH)_2O_2$, and with it as coloring matter of secondary importance *purpurin,* $C_{14}H_5(OH)_3O_2$. Besides these two technically important constituents there have been recognized *pseudopurpurin,* an orange dye color, and a yellow one (*xanthopurpurin*). These coloring matters, however, are probably decomposition products from glucosides existing in the fresh plant. Thus, alizarin is known to result along with glucose from the treatment with dilute acids of *rubianic* or *ruberythric acid,* $C_{26}H_{28}O_{14}$, according to the reaction:

$$C_{26}H_{28}O_{14} + 2H_2O = C_{14}H_8O_4 + 2C_6H_{12}O_6$$

The most interesting of the coloring substances is the *alizarin,* and this is now termed *dihydroxy-*

anthraquinone, $C_{14}H_8O_{14}$. This occurs as orange-red crystals, almost insoluble in cold water, but readily soluble in alcohol, ether, the fixed oils, and alkaline solutions. The alcoholic and aqueous solutions are rose-colored; the ethereal, golden yellow; the alkaline, violet and blue when concentrated, but violet-red when sufficiently diluted. A beautiful rose-colored lake is produced by precipitating a mixture of the solutions of alizarin and alum. Alizarin was recognized by Graebe and Liebermann in 1868 as a derivative of anthracene, $C_{14}H_{10}$—a hydrocarbon contained in coal tar—and in the same year they elaborated a method for preparing it commercially from anthracene. Upon this arose rapidly a great chemical industry, and the cultivation of madder, has, of course, decreased correspondingly.

Madder is used in *amenorrhea* and *dropsy*, and when taken into the stomach imparts a red color to the milk and urine, and to the bones of animals, without sensibly affecting any other tissue. The effect is observable most quickly in the bones of young animals, and in those nearest the heart. Under the impression that it might effect some change in the osseous system, it has been prescribed in *rachitis*, but without favorable result. *Dose*, about half a drachm (2.0 Gm.), repeated three or four times a day.

Rubidium.—Salts of *rubidium* may be obtained much more cheaply than in former years, on account of Erdmann's process for the recovery of these salts from the Stassfurt potash deposits. Several salts have been brought forward for use in practical medicine.

Rubidium iodide, RbI, which occurs in whitish crystals, freely soluble in water, has been recommended by Harnack, Neisser, and others as a substitute for potassium iodide, than which it is asserted to be better borne by the stomach. The dose is that of potassium iodide. G. Jacontini affirms that rubidium iodide is a specific in *coryza*.

Rubidium bromide, RbBr, may be used as a substitute for, and in the dose of, potassium bromide, than which it is said to be better borne, especially by feeble patients.

Rubidium and Ammonium Bromide ($RbBr + 3NH_4Br$).—A white or slightly yellowish, crystalline powder, readily soluble in water. Its taste is somewhat cooling at first, and pungently saline afterwards. This salt, one hundred parts of which contain thirty-six parts of rubidium bromide and sixty-four of ammonium bromide (NH_4Br) is used as a hypnotic in *doses* of from one to two drachms (3.9–7.7 Gm.) in a day.

Rubidium Sulphate. Rb_2SO_4.—This occurs as large, rhombic crystals with a taste resembling potassium sulphate. It is soluble in water and is stated to be a very active cathartic.

Rubus. *N. F. IV. Blackberry Bark. Bramble. Finger Berry, Ecorce de Ronce Noir*, Fr. *Brambeeren, Brombeerrinde*, G.—"The dried bark of the rhizome of *Rubus villosus* Aiton, *Rubus nigrobaccus* Bailey, or of *Rubus cuneifolius* Pursh (Fam. *Rosaceæ*)." *N. F.* Of the genus Rubus a large number of species are indigenous in the United States, where they are called by the various names of *blackberry, dewberry, cloudberry*, etc. Most of them are shrubby or suffruticose briers, with astringent roots and edible berries; some have annual stems without prickles. They are naturally divided into the *raspberries*, in which the edible fruit is composed of pulpy, one-seeded, coherent little drupes, separate from the dry receptacle, and the *blackberries*, in which the receptacle is juicy and coheres with the drupes to form the fruit. The National Formulary recognizes as the source of rubus only three species, but it is probable that others contribute to the bark of the markets. In fact, the U. S. Pharmacopœia of 1890 recognized officially *R. canadensis* L., and *R. trivialis* Michaux.

The blackberry root is branching, cylindrical from 0.5 to 2.5 cm. in thickness, and covered with a thin bark, which is externally of a light brownish or reddish-brown color, and in the dried root is wrinkled longitudinally. The dewberry root is usually smaller, without the longitudinal wrinkles, but with transverse fissures through the epidermis, and of a dark ash color, without any reddish tinge. Both are inodorous. The National Formulary IV describes blackberry bark as follows: "In elongated, tough, flexible quills or bands, from 3 to 6 mm. in diameter, the bark from 1 to 2 mm. in thickness; outer surface deep red-brown or dark gray-brown, occasionally blackish-brown, somewhat scaly; inner surface yellow or pale brown, strongly and coarsely long straight-striate; fracture tough-fibrous; readily splitting. Inodorous; taste strongly astringent and bitter. Rubus yields not more than 5 per cent. of ash." *N. F.* Blackberry bark was official in the U. S. VIII, but it was deleted, and the National Formulary IV admitted it under the name of Rubus. Its virtues are extracted by boiling water and by diluted alcohol, and depend chiefly upon tannin, which is an abundant constituent. The woody part of the roots is inert.

Dewberry and blackberry roots have long been a favorite domestic astringent remedy in *diarrheas*. Given in decoction, they are usually acceptable to the stomach, without being offensive to the taste. The decoction may be prepared by boiling an ounce of the smaller roots, or of the bark of the larger, in a pint and a half of water down to a pint, of which from one to two fluidounces (30 to 60 mils) may be given to an adult three or four times, or more frequently, during the twenty-four hours.

A fluidextract and compound elixir of rubus are in the N. F.

The fruit is official in the N. F. under the English title **Blackberries**, *N. F. IV. Rubi Fructus*. It is described by the N. F. as "The fresh, ripe fruit of varieties of *Rubus nigrobaccus* Bailey or *Rubus villosus Aiton* (Fam. *Rosaceæ*). An aggregate fruit, ovate to oblong, rounded or slightly pointed, composed of numerous, shining black drupelets attached to an esculent receptacle; pericarp externally smooth or with only a few hairs (*R. villosus*), mesocarps fleshy, juice purple-red, endocarps hard, black, surfaces deeply wrinkled." *N. F.*

The fruit of *Rubus Iodœus* is official in the N. F. under the English title **Raspberries**, *N. F. IV. Rubi Idæi Fructus*. They are described as "The fresh, ripe fruit of varieties of *Rubus Idœus* Linné or of *Rubus strigosus* Michaux (Fam. *Rosaceæ*). An aggregate fruit, globular or hemispherical with a concave depression at the base where separated from the receptacle, composed of twenty or more small, rounded-polygonal, succulent drupelets; pericarps externally red, hairs numerous; mesocarps fleshy, juice red; endocarps small stones with wrinkled surfaces. Odor characteristic, aromatic; taste pleasant, sweet, acidulous. For pharmaceutical purposes, Black Raspberries, the fresh ripe fruit of varieties of *Rubus occidentalis* Linné

(Fam. *Rosaceæ*), may be substituted either in part or wholly for Red Raspberries." *N. F. Rubus strigosus* has yielded to cultivation certain superior raspberries, especially those which have been known commercially as the Cuthbert and Hansall raspberries. *Rubus neglectus* Peck, the purple wild raspberry, with a fruit which varies from dark red or purple to yellowish in cultivation, has also yielded a commercial raspberry.

Raspberries are employed for the production of the N. F. syrup (see Part III).

The *Rubus occidentalis* L., *black raspberry* or *thimbleberry* of the Northern United States, which is also cultivated, is sometimes employed for the making of a raspberry syrup, but yields a very inferior product.

Rubus Chamæmorus L. *Cloud Berry. Baked-Apple Berry.* (Fam. *Rosaceæ.*)—This plant, which inhabits the northern portions of both continents, is largely employed in Northern Russia, in the form of an infusion of the berries or leaves, as a diuretic in *dropsy.* The fruits are about 2 cm. in diameter, of an amber color, and very juicy when ripe. Popoff found in it a crystallizable acid which is an essential diuretic, acting directly upon the renal secreting structures without affecting either cardiac action or arterial tension. (*Vrach.*, iv, 1886.)

Rumex. *N. F. IV. Yellow Dock. Curled Dock. Radix Lapathi.—Rumex* was official in the U. S., 1890, and has been admitted to the N. F. IV and is defined as "The roots of *Rumex crispus* Linné, or of *Rumex obtusifolius* Linné (Fam. *Polygonaceæ*), without the presence of more than 5 per cent. of stem bases." *N. F. IV.* The roots of rumex are officially described as "Usually split longitudinally or cut into transverse pieces about 2 cm. in length. The entire root, nearly simple, slightly tapering, with few if any rootlets, somewhat twisted, up to 30 cm. in length and 7 cm. in diameter, externally reddish-brown or grayish from adhering soil, finely annulate above, deeply wrinkled longitudinally, marked with small indented root scars which are often transversely elongated and with occasional stem scars or remains of stem, the latter being hollow and finely striated; leaf buds few, obconical; fracture short and dusty, somewhat fibrous. The transverse section exhibits a yellowish or brownish cortex and a whitish or yellowish wood which is finely radiate in the outer portion. When examined under the microscope, it exhibits a thick cortex with several layers of cork, beneath which is an interrupted row of stone cells; a distinct cambium; and vascular bundles with few fibers. The **powder**, when examined under the microscope, shows calcium oxalate crystals in rosette aggregates from 0.025 mm. to 0.06 mm. in diameter; numerous starch grains ellipsoidal or narrowly elongated, sometimes truncate, up to 0.025 mm. in length; stone cells from 0.04 mm. to 0.2 mm. in diameter, with walls somewhat lamellated, from 0.008 mm. to 0.025 mm. in thickness and with few simple pores; sclerenchymatous fibers few, thin-walled with simple pores; tracheæ up to 0.1 mm. in width with scalariform or reticulate thickenings of the wall; cork cells light brown. Rumex yields not more than 10 per cent. of ash." *N. F. IV.*

Several species of rumex have sour leaves, and are distinguished by the common name of *sorrel* from the others, which are called *dock.* Of the former, *Rumex Acetosa* L., or *common English sorrel*, formerly held a place in the London and Dublin Pharmacopœias. *R. Acetosella* L. is the common sorrel of our fields, though supposed to have been originally introduced from Europe. The leaves of both these plants are agreeably sour to the taste, and owe their acidity to acid potassium oxalate with a little tartaric acid. They quite lose this taste in drying. They are refrigerant and diuretic, and may be used advantageously as an article of diet in *scurvy.* For this purpose they are prepared in the form of salad. The juice of the leaves forms with water an agreeable acidulous drink, sometimes used in fevers. Taken very largely, the leaves are said to have produced poisonous effects. *R. scutatus* L., of Europe, Northern Africa, Asia Minor, and the Caucasus, also ranks among the sorrels (*French sorrel*).

Of the proper docks, the roots of *R. silvestris* Wallr., an European plant, and of *R. conglomeratus* Murr., *R. aquaticus*, *R. sanguineus* L., and *R. Patientia* L., belonging both to Europe and to the United States, may be employed indiscriminately with those of the *R. crispus* L., which was formerly recognized by the U. S. Pharmacopœia. *R. Britannica* L., and *R. obtusifolius* L., were formerly official. *R. Hydrolapathum* Hudson, which is the *R. aquaticus* of the old Dublin Pharmacopœia, is thought to be the *Herba Britannica* of the ancients, celebrated for the alleged cure of *scurvy* and diseases of the skin. The docks are herbaceous plants with perennial roots, and especially distinguished by the sheathing petioles of the leaves. The flowers are small, mostly green, and occur in terminal or axillary panicles.

Dock root, from whatever species derived, has an astringent, bitter taste, with little or no odor. The leaves of most of the species are edible when young, and are occasionally used like spinach. They are somewhat laxative, and form an excellent diet in scorbutic cases. The roots are used to dye a yellow color. According to J. H. Salisbury (*N. Y. Journ. Med.*, March, 1855), the petioles of the leaves contain nearly one per cent. of oxalic acid; the cortical part of the root, which is the most active, yielded, on analysis, starch, a little sugar, albuminous matter, gummy matter, bitter extractive, tannic acid of the kind which gives green precipitates with the salts of iron, lignin, and various salts. The root yields its virtues to water and to alcohol, but is injured by long boiling.

Dock root is astringent, gently tonic, and has been supposed to have alterative properties, making it useful in skin diseases and even *syphilis.* From the root of *R. Nepalensis* Wall., which is largely used in Madras as an astringent for medicinal purposes and for dyeing, O. Hesse has separated three crystalline substances to which he gives the names of *rumicin*, *nepalin*, and *nepodin.* (*P. J.*, lvi; also *Proc. A. Ph. A.*, 1896, 551.) According to Tutin and Clewer (*Trans. Chem. Soc.*, 1910, xcvii) the *R. Eckolianus* Meissner, a South African herb, contains chrysophanic acid, emodin, and allied products, and is mildly purgative. Tschirch and Weil found small quantities of *emodin* and *chrysophanic acid* with *lapathinic acid*, $C_{20}H_{18}O_{14}$, in the root of *R. obtusifolius.* (*A. de Pharm.*, 1912, No. 1, 20.) *R. aquaticus* and *R. Britannica* are the most astringent. The roots of some species unite a laxative with the tonic and astringent property, resembling rhubarb somewhat in their operation. Such are those of *R. crispus* and *R. obtusifolius;* and *R. alpinus* L., has in some parts of Europe the name of *mountain rhubarb.* This resemblance is not singular, as the two genera belong to the same natural family. A. Gilbert and P. Lereboullet have discovered a remarkable prop-

erty of *Rumex crispus*. For the roots of this plant are said to possess the power of taking up the iron present in the soil, and fixing it in the form of organic compounds of iron. By watering the plants with a solution of iron carbonate, roots are said to be obtained which contain 1.5 per cent. of iron. Rumex is said to give good results in the treatment of *chlorosis* and *anemia*. The authors gave the dried and powdered root during meals in doses of fifteen to forty-five grains (1–3 Gm.), in view of their good results they regard it as a valuable iron medicine. Dock root is given in powder or in decoction. Two ounces (62 Gm.) of the fresh root bruised, or one ounce (31 Gm.) of the dried, may be boiled in a pint (480 mils) of water, of which two fluidounces (60 mils) may be given at a *dose*, and repeated as the stomach will bear it. George G. Flemyng (*L. L.*, i, 1896) reported the death of two sisters, aged respectively five and six and a half years, preceded by symptoms of oxalic acid poisoning as the result of the ingestion of sorrel leaves.

Ruta.—Under this name the U. S. Pharmacopœia formerly recognized *Ruta graveolens* L.; *Rue; Rue odorante*, Fr.; *Garten-Raute*, G.; Ruta, It.; *Ruda*, Sp., (Fam. *Rutaceæ*). It is a low, shrubby plant, with several shrubby branching stems, which, near the base, are woody and covered with a rough, bark, but in their ultimate ramifications are smooth, green, and herbaceous. The leaves are fleshy, 2- to 3-pinnatified, the ultimate lobes or divisions being obovate-cuneate. The flowers are yellow, and disposed in a terminal branched cyme. The plant is a native of the south of Europe, locally established in pastures in the United States and cultivated in our gardens. The whole herb is active, and yields its properties to water and alcohol. The leaves have a strong, disagreeable odor, especially when rubbed. Their taste is bitter, hot, and acrid. When recent, and in full vigor, they have so much acrimony as to inflame and even blister the skin, if much handled; but the acrimony is diminished by drying. Their virtues depend chiefly on a volatile oil, which is contained in glandular vesicles, apparent over the whole surface of the plant. They contain, also, according to Bornträger, a peculiar acid which he calls *rutinic acid*, $C_{25}H_{28}O_{15}$ (or $C_{27}H_{32}O_{16}$, according to later writers). Rutinic acid is the coloring principle of rue, and has been found in various other plants; though, like quercitrin, yielding quercetin and sugar, it has been shown to be distinct. (*J. P. C.*, 1862, 165.)

Rue yields a very small proportion of a yellow or greenish volatile oil (*Oleum Rutæ, U. S.*, 1880), which becomes brown with age. According to Zeller, the yield from the fresh herb is 0.28 per cent., that from the seeds about 1 per cent. The oil has the strong unpleasant odor of the plant, and an acrid taste. Kane gives its sp. gr. at 0.837, its boiling point at 230° C. (446° F.). "A neutral reaction. Sp. gr. about 0.880. It is soluble in an equal weight of alcohol." *U. S.*, 1880. It consists mainly of an oxidized constituent, which Strecker proved to be *methyl-nonyl-ketone*, $CH_3.CO.C_9H_{19}$; that is, a ketone analogous to acetone, $CH_3.CO.CH_3$. This accounts for its yielding under treatment with oxidizing agents, pelargonic acid, $C_9H_{18}O_2$. The methyl-nonyl-ketone, when pure, is a colorless liquid, fluorescing blue, boiling at 225° C. (437° F.), and crystallizing at about 15° C. (59° F.). Schimmel & Co. (*Schim. Rep.*, 1892, 31) state that pure oil of rue consists of 90 per cent. of methyl-nonyl-ketone, and solidifies even at a moderate temperature to a solid, crystalline mass, and has the sp. gr. 0.837.

According to von Soden and Henle, *Algerian oil of rue* differs from the ordinary oil in that it is chiefly composed of *methyl-heptyl-ketone*, with but small quantities of *methyl-nonyl-ketone*. Its specific gravity at 15° C. (59° F.) is 0.842; and it does not solidify at −15° C. (5° F.). (*Ph. Ztg.*, 46.) Frederick B. Power and Frederic H. Lees (*Trans. Chem. Soc.*, 1902) have since published an elaborate investigation of a similar Algerian oil. They find 80 per cent. of the two ketones, methyl-heptyl-ketone and methyl-nonyl-ketone, 10 per cent. of the corresponding carbinols (alcohols), pinene, l-limonene, cineol, methyl salicylate, ethyl valerate, and some free fatty acids.

Rue is said to have been used by the ancients as a condiment. In modern times it has been employed in *hysteria, worms, colic*, and atonic *amenorrhea* and *menorrhagia*. Its medicinal activity depends upon its volatile oil, which is a powerful local irritant, causing, when applied to the skin persistently, burning, redness, and vesication, and when taken internally in large doses, violent gastric pains and vomiting, great prostration, confusion of mind, convulsive twitching, and in pregnant women, abortion. It has been considerably used in Europe for the production of criminal abortion, in a number of cases with fatal results. In a case of fatal poisoning in a man, reported by G. F. Cooper, there were vomiting, violent tormina and tenesmus, with bloody stools, great abdominal distention, with tenderness and severe strangury. (*Med. Exam.*, N. S., ix, 720.) The *dose* of the oil is from two to five minims (0.12–0.3 mil) every two or three hours. The rue itself is sometimes given in the *dose* of from ten to thirty grains (0.65–2.0 Gm.).

Ruthenium Chloride. *Ruthenium Sesquichloride.* Ru_2Cl_6.—A deliquescent, crystalline mass of a brownish-red color and soluble in water and stated to possess a high antiseptic value.

Ruthenium Red. *Ruthenium Oxychloride Ammoniated.* $Ru_2(OH)_2Cl_4.7(NH_3) + 3H_2O$.—A brownish-red powder, soluble in water. It is used as a microscopic stain and reagent for pectin, plant mucin, and gum. In bacteria staining there must be added to the *ruthenium red* a small amount of acetic acid.

Rye. *Secale cereale* L. (Fam. *Gramineæ.*) *Roggen*, G. *Leigle*, Fr. *Centeno*, Sp.—*Rye* is allied to wheat and barley. Its native country is somewhat doubtful, but is said to be found wild throughout the Mediterranean countries, extending to Central Asia. There are two prominent varieties known as "Winter" and "Spring" rye, the difference being due to cultivation mainly. Rye is now cultivated in all temperate latitudes. The average composition of rye as a cereal may be thus stated: fat, 1.43 per cent.; starch, 61.87 per cent.; sugar (as sucrose), 4.30 per cent.; albumen (insoluble in alcohol), 9.78 per cent.; nitrogenous matter (soluble in alcohol), 5.09 per cent.; cellulose, 3.23 per cent.; mineral matter, 1.85 per cent.; moisture, 12.45 per cent. (Sadtler, *Industrial Organic Chemistry*, 3d ed., p. 169.) *Rye flour* is used, in the dry state, as an external application to *erysipelatous inflammation* and other eruptive affections, the burning and unpleasant tingling of which it tends to allay, while it absorbs the irritating secretions. In the form of mush it is an excellent laxative article of diet, and, mixed with molasses, it may be given with great advantage in *hemorrhoids* and *prolapsus ani*,

connected with *constipation*. Rye carbonized by heat, with exclusion of the air, has been highly recommended as a tooth powder.

Sabadilla. *Cevadilla.*—The dried ripe seeds of *Schoenocaulon officinale* (Schlecht.) A. Gray [*Asagræa officinalis* (Cham. and Schlecht.) Lindl.], were recognized by the Br. Pharm. of 1885. At one time cevadilla was generally believed to be derived from *Veratrum Sabadilla* Schiede. The plant grows in the Andes of Mexico and in the mountains of Guatemala and Venezuela. It is also cultivated. The fruit is a capsule having three locules in each of which there are from three to four seeds. A resemblance, existing or supposed, between this fruit and that of barley is said to have given rise to the Spanish name cevadilla, which is a diminutive of barley. The seeds are elongated, pointed at each end, flat on one side and convex on the other, somewhat curved, 5 to 8 mm. long, wrinkled, slightly winged, black or dark brown on the outside, whitish within, hard, inodorous, and of an exceedingly acrid, burning, and durable taste.

Pelletier and Caventou first noted the presence of an alkaloid in cevadilla, which base they called *veratrine;* Meissner in the same year announced the presence of an alkaloid, *sabadilline*, $C_{34}H_{53}O_8N$, and Couërbe, Merck, and Weigelin all described what they considered as distinct bases; but its exact composition remained unsettled until Wright and Luff (*J. Chem. S.*, 33, 338) found in it three bases: (1) *cevadine*, $C_{32}H_{49}O_9N$, (agreeing with the base described by Merck as veratrine), crystallizing in needles or compact crystals, fusing at 205° C. (401° F.) (202° C. (395.6° F.), according to Merck), insoluble in water, easily soluble in alcohol and ether, and decomposed by hot alcoholic potash into *cevine*, $C_{27}H_{43}O_8N$ ($C_{27}H_{45}O_9N$, Flückiger), and *methyl-crotonic acid* (*cevadic acid* of Pelletier and Caventou), $C_5H_8O_2$; (2) *veratrine*, $C_{37}H_{53}O_{11}N$, obtained from the syrupy mother liquor from which the cevadine has crystallized (see p. 1194); (3) *cevadilline* or *sabadilline*, $C_{34}H_{53}O_8N$, obtained after the extraction of the veratrine with ether; it is insoluble in ether, slightly soluble in boiling benzene, and readily soluble in fusel oil, uncrystallizable, and appears to yield methyl-crotonic acid on treatment with alcoholic soda. For method of extracting the alkaloids, see *U. S. D.*, 19th ed., p. 1636.

Merck has since (*M. R.*, Jan., 1891, 3–9) isolated two new alkaloids from cevadilla, which he names *sabadine* and *sabadinine* respectively. The former has the formula $C_{29}H_{51}NO_8$, crystallizes from ether in short needles, and fuses at from 238° to 249° C. (460.4°–464° F.). It dissolves in concentrated sulphuric acid with a yellow color and a green fluorescence, which gradually disappears, while the liquid assumes a blood-red and then violet color. The alkaloid is sternutatory, although in a much less degree than veratrine. The second alkaloid crystallizes from ether in filiform needles, which begin to sinter at 160° C. (320° F.), but show no fixed fusing point. Concentrated sulphuric acid causes a permanent blood-red color. The formula is given as $C_{27}H_{45}NO_8$. This alkaloid is not sternutatory. Cevadilla yields about 0.3 per cent. of veratrine. (See *Veratrina*, p. 1194.)

Cevadilla is an acrid, drastic emeto-cathartic, operating occasionally with great violence, and in overdoses capable of producing fatal effects. Known in Europe as early as 1752, and formerly used to some extent as a tænicide, in *doses* of from five to twenty grains (0.32–1.3 Gm.), it was official solely as the source of veratrine. It is the principal ingredient of the *pulvis capucinorum*, sometimes used in Europe for the destruction of vermin in the hair.

According to E. Falk, 0.001 Gm. of pure cevadine will paralyze the frog; 0.01 Gm. will cause death from cardiac paralysis in rabbits; 0.02 Gm. per kilogramme produces paralysis, interrupted by tetanic spasms. Cevine was found to be much less poisonous than cevadine, though producing similar symptoms.

Sabbatia. *American Centaury. Centaurée Américaine*, Fr. *Sabbatie*, G.—The overground plant of *Sabatia* (*Sabbatia*) *angularis* (L.) Pursh. (Fam. *Gentianaceæ*), an herb found in rich soil throughout the Eastern and Central United States and Ontario. The stems are much branched, distinctly 4-angled, and from 3 to 9 dm. high. The leaves are ovate, 5-nerved, having a heart-shaped clasping base. The flowers are rose-pink and on drying become pinkish-brown. The fruit is a 2-valved capsule, dark brown and covered with a resin. It is more or less used in popular medicine as a tonic and antiperiodic. It is a simple bitter of some activity, and may very well be substituted for the foreign remedies of its class. Rodney H. True found American centaury adulterated with *Rhexia mariana*, also known as *deer grass* or *meadow beauty*. (*A. J. P.*, 1905, 213.) John F. Huneker found in *sabbatia* a small proportion of *erythrocentaurin*, $C_{27}H_{24}O_8$, previously discovered by Méhu, a French chemist, in *Erythræa Centaurium* Pers., of Europe.

In the Southeastern United States, the *Sabbatia Elliottii* Steud., or *Quinine flower*, and in the Southwestern United States the *Sabbatia campestris* Nutt. have been employed like the *S. angularis* in the North. According to Merck the *S. Elliottii* contains a glucoside, *sabbatin*, as its active principle. Of the *S. angularis* and the *S. campestris* the whole plant is used, the *dose* being a drachm (3.9 Gm.), given in the form of fluidextract or in decoction. Of the quinine flower, the root is employed; *dose*, of the fluidextract, one fluidrachm (3.75 mils); in intermittent fever to be repeated at short intervals.

Sabina. *U. S. VIII. Savin. Sabinæ Cacumina. Summitates* (*Herba*) *Sabinæ. Savine Tops. Sabine*, Fr. Cod. *Sevenbaum. Sadebaumspitzen. Sevenkraut*, G. *Sabina*, It., Sp.—"The tops of *Juniperus Sabina* Linné (Fam. *Coniferæ*)." *U. S. VIII. Juniperus Sabina* is an evergreen shrub from three to fifteen feet high, with numerous erect, pliant branches. The leaves, which completely invest the younger branches, are numerous, small, erect, firm, smooth, pointed, dark green, glandular in the middle, opposite, and imbricated in four rows. The fruit is a blackish-purple berry of an ovoid shape, and containing three seeds. The savin is a native of the south of Europe and the Levant, and grows wild in the neighborhood of the northwestern lakes of the United States.

The ends of the branches, and the leaves by which they are invested, are collected for medicinal use in the spring. When dried they are very much faded in color. They were officially described as "short, thin, subquadrangular branchlets bearing leaves which are rather dark green, in four rows, opposite, scale-like, ovate-lanceolate, more or less acute, appressed, imbricated, having on the back a shallow groove containing an oblong or roundish gland; odor peculiar, terebinthinate; taste disagreeable, resinous and bitter." *U. S.* They have a strong, heavy, disagreeable odor, and a

bitter, acrid taste. These properties, which are less striking in the dried than in the recent leaves, are owing to a volatile oil. The leaves impart their virtues to alcohol and to water. C. H. Needles found in them volatile oil, gum, tannic or gallic acid, resin, chlorophyll, fixed oil, bitter extractive, lime, and salts of potassium. (*A. J. P.*, xiii, 15.)

In America the tops of *Juniperus virginiana* L., or common *red cedar*, also commonly referred to as *savin*, are sometimes substituted in commerce for savin, which they resemble closely, but from which they can be distinguished by some of their leaves being obtuse or acutish and the fruits being smaller, purplish and containing fewer seeds. In Europe savin is said to be adulterated with the tops of *J. phœnicea* L., which contain volatile oil similar to that of *J. communis*. Such substitution is to be detected by the fact that in *J. phœnicea* the imbricated leaves occur in spirals of five, and the berries are large, shiny, and vary in color from yellow to reddish-yellow. In the mesophyll there occur large stone cells which are either single or in groups.

According to the more recent authorities, the proportion of volatile oil obtained from savin varies as much as from 1 to 2.5 per cent. The *oil of savine* (*Oleum Sabinæ, U. S. VIII*) is "a colorless or yellowish liquid, having a peculiar terebinthinate odor, and a pungent, bitter, and camphoraceous taste. Specific gravity: 0.903 to 0.923 at 25° C. (77° F.). The Oil is dextrogyrate, the angle of rotation varying between + 40° and + 60° in a 100 Mm. tube, at a temperature of 25° C. (77° F.). Soluble in about one-half volume or more of 90 per cent. alcohol." *U. S.* According to Schimmel & Co. (*Schim. Rep.*, April, 1897), its specific gravity is from 0.91 to 0.925, optical rotation + 45° to + 60°, and it contains *pinene*, $C_{10}H_{16}$, *cadinene*, $C_{15}H_{24}$, and an alcohol, $C_{10}H_{16}O$, *sabinol*, which is present both in the free state and as acetic ester. With iodine it becomes heated, detonates, and gives off yellow and violet-red vapors. (Flaschoff.)

Savin is highly irritant, and is supposed to have a special direction to the uterus. It has been much used in *amenorrhea* and *atonic menorrhagia*, and occasionally as a remedy for *worms*. Chapman strongly recommended it in *chronic rheumatism*, and it is employed in Germany, both internally and externally, in *chronic gout*. In overdoses it may produce dangerous gastro-intestinal inflammation, and it should therefore be used with caution. In no case should it be employed when much general or local excitement exists. In pregnancy it should always be given with great caution. As an external irritant, savin is useful, in the form of cerate, for maintaining a discharge from blistered surfaces; but as in this country savin ointment is often feeble, either from the age of the drug or from the substitution of red cedar, it has fallen into disrepute. In powder or infusion, savin is used in Europe as an application to *warts, indolent* or *gangrenous ulcers, psora*, and *tinea capitis*, and the expressed juice of the fresh leaves, diluted with water, is sometimes used for similar purposes. Powdered savin should not be used after it has lost the green color, characteristic of the fresh drug. The oil of savin is a powerful local irritant, producing, when persistently applied to the skin or the mucous membrane, violent inflammation. It has been much used for the purpose of producing criminal abortion, and in a number of such cases has caused death, the symptoms being violent abdominal pain, bloody vomiting and purging, diminution or suppression of urine, disordered respiration, unconsciousness, convulsions, and fatal collapse. Although Prochnow (*A. I. P. T.*, 1911, xxi, p. 316) has found that small doses of savin have a slight stimulating effect upon the uterus it is manifest that any abortifacient results must be due to general disturbance of the health rather than to any local action. The fluidextract is rarely used internally but the stated dose is from five to ten minims (0.3–0.6 mil). The *dose* of the oil of savin is from one to three minims (0.06–0.2 mil).

Fluidextract of Savin. Fluidextractum Sabinæ. U. S. VIII.—The U. S. VIII gave the following directions for the preparation of the fluidextract: "Savin, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *two hundred and fifty mils* [or 8 fluidounces, 218 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Savin is exhausted. Reserve the first *nine hundred mils* [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]." *U. S. VIII*

Sabromin. *N. N. R.* 1917. *Dibrom-behenate of Calcium.* $(C_{22}H_{41}O_2Br_2)_2Ca$.—This is a white powder without taste or odor prepared by adding bromine to erucic acid, forming *dibrombehenic acid*, and then preparing the calcium salt of the latter. It is insoluble in alcohol, water and acetone, soluble in ether and chloroform, and contains after drying 29 per cent. bromine and 3.8 per cent. calcium. The clinical evidence is indisputable that this preparation is capable of exercising many of the therapeutic properties of the alkaline bromides, but there is considerable contradiction as to the extent to which it may replace the older salt. On the one hand, Von Mering (*M. K.*, iv, p. 1464) has found, despite the fact that it contains only one-half the amount of bromine that potassium bromide does, it is equal in power although slower in action, and Bratz and Schlokow (*D. M. W.*, 1909) assert that weight for weight *sabrominin* is more efficacious than potassium bromide. On the other hand, Ellinger and Kotake (*A. E. P. P.*, 1911, lxv) assert that if administered in large enough doses to obtain the bromide action, sabromin is injurious to the kidney, and Bittner (*Pr. M. W.*, 1910) found it of little use in *epilepsy*. It has been employed by many physicians with mostly favorable results in *hysteria, neurasthenia, insomnia, epilepsy*, and other conditions in which the bromides are habitually employed. The *dose* ordinarily given is from eight to thirty grains (0.5–2.0 Gm.).

Saccharosolval.—This preparation is a combination of ortho-oxybenzoic acid, trypsin, and the spinal marrow of oxen. It is administered in the treatment of *diabetes*, forty-five grains (3 Gm.) being given three times a day.

Safrol. *Safrolum. U. S. VIII. Synthetic Oil of Sassafras. Safrol*, Fr., G. $C_{10}H_{10}O_2 = 162.08$. —"The methylene ether of allyl pyrocatechol [C_6

$H_3.C_3H_5.(OOCH_2)$ 1 : 3 : 4], found in oil of sassafras, camphor oil, and other volatile oils, purified, if necessary, by repeated chilling and crystallization." *U. S. VIII. Safrol* is found in oil of sassafras often in the proportion of 80 per cent., but commercially it is obtained from the red oil of camphor, by fractional distillation, the portion boiling at about 230° C. (446° F.) contains the safrol, this is cooled and the crystals separated. (See *Oleum Sassafras*, p.790.) It was officially described as "a colorless or faintly yellow liquid with a sassafras-like odor. Specific gravity: 1.098 to 1.100 at 25° C. (77° F.). Boiling point: about 233° C. (451.4° F.). It is optically inactive. On cooling to –20° C. (–4° F.) or below, it solidifies to a mass of crystals, which do not melt below 11° C. (51.8° F.). Soluble in about an equal volume of strong alcohol, and in about 30 parts of 70 per cent. alcohol. Miscible in all proportions with ether and chloroform." *U. S. VIII.* Physiologically and therapeutically, safrol is equivalent to oil of sassafras. *Dose*, three to eight minims (0.2–0.5 mil).

Sagapenum.—This gum-resin, formerly highly esteemed, but at present very rarely met with even in Eastern commerce, is the concrete juice of a Persian plant, *Ferula Persica* Willd. (Fam. *Umbelliferæ*), related to those that yield galbanum. It is in irregular masses, composed of agglutinated fragments, slightly translucent, of a brownish-yellow, olive, or reddish-yellow color externally, paler internally, brittle, of a consistence somewhat resembling that of wax, and often mixed with impurities, especially with seeds more or less entire. An inferior variety is soft, tough, and of uniform consistence. It has an alliaceous odor less disagreeable than that of asafetida, and a hot, nauseous, bitterish taste. It softens and becomes tenacious by the heat of the hand. The effect of time and exposure is to harden and render it darker. It is inflammable, burning with a white flame and much smoke, and leaving a light spongy charcoal. Pure alcohol and water dissolve it partially, diluted alcohol almost entirely. Distilled with water it affords a small quantity of volatile oil, and the water is strongly impregnated with its flavor. According to Tschirch (*Harze und Harzbehälter*, 229), it contains 23.3 per cent. of gum; 19.2 per cent. of essential oil, containing sulphur; and 57.5 per cent. of a resin which is free from sulphur and melts at 74° to 76° C. (165.2°–168.8° F.). The ether soluble resin of *sagapenum* can be separated by saponification into *umbelliferone* and *sagaresitannol*, $C_{24}H_{37}O_4.OH$. This latter yields on oxidation *oxypicric acid*. The oil is pale yellow, very fluid, lighter than water, and of a disagreeable alliaceous odor. Sagapenum was formerly used in *doses* of from ten to thirty grains (0.65–2.0 Gm.) in *amenorrhea*, *hysteria*, etc.; also externally in plasters as a discutient.

Sage. *Salvia. U. S. VIII. Garden Sage. Meadow Sage. Save. Picked Sage. Sauge Officinale*, Fr. Cod. *Sauge*, Fr. *Folia Salviæ*, P. G. *Salbei*, G.—"The dried leaves of *Salvia officinalis* Linné (Fam. *Labiatæ*)." *U. S. VIII. Salvia officinalis*, or common garden *sage*, is a perennial plant, about two feet high, with a quadrangular, pubescent, branching, shrubby stem, furnished with opposite, petiolate, ovate-lanceolate, crenulate, wrinkled leaves, of a grayish-green color, sometimes tinged with red or purple. The flowers are blue, variegated with white and purple, and are disposed on long terminal spikes, in distant whorls, each composed of a few flowers, and provided with ovate, acute, deciduous bracts. The calyx is tubular and striated, with two lips, of which the upper has three acute teeth, the under two. The corolla is tubular, bilabiate, ringent, with the upper lip concave, and the lower divided into three rounded lobes, of which the middle is the largest. The filaments are supported upon short pedicels, to which they are affixed transversely at the middle.

Sage grows spontaneously in Southern Europe, and is cultivated abundantly in our gardens. There are several varieties, differing in the size and color of their flowers, but all possessing the same medicinal properties. The flowering period is in June, at which time the plant should be cut, and dried in a shady place. The leaves were officially described as "long and stoutly petiolate, the blade elliptical or ovate-oblong, 3 to 7 Cm. long, obtuse or subacute at the summit, rounded or subcordate at the base, finely crenulate, thick, grayish-green, very pubescent, especially on the under surface, conspicuously reticulate-veined; odor aromatic; taste aromatic, bitter, and somewhat astringent." *U. S. VIII.*

Both the leaves and the flowering summits have a strong, fragrant odor, and a warm, bitterish, aromatic, somewhat astringent taste. They abound in a volatile oil, which may be obtained separate by distillation with water. Muir (*J. Chem. S.*, 37, p. 678) found it to contain a terpene boiling at 156° C. (312.8° F.), another boiling at 171° C. (339.8° F.), *thujone*, $C_{10}H_{16}O$, a liquid boiling at from 197° to 203° C. (386.6°–397.4° F.), and ordinary camphor, $C_{10}H_{16}O$. In the fresh oil the first terpene predominates. On standing, the amount of *thujone* increases, and then the camphor. The oil from English leaves contains also a sesquiterpene, $C_{15}H_{24}$, of the boiling point 260° C. (500° F.). Wallach (*Ann. Ch. Ph.*, 1889) states that the first portions contain pinene and cineol, but the greater portion consists of thujone, $C_{10}H_{16}O$ (formerly called *salviol*). Ferrous sulphate strikes a black color with infusion of sage.

Sage unites slightly tonic, astringent, and aromatic properties. By the ancients it was highly esteemed; it is at present little used, except as a condiment, but has been given in *dyspepsia*, also for *colliquative sweats*. According to Cadéac and Meunier (*Lyons Méd.*, May, 1891), the volatile oil of sage is a violent epileptiform convulsant, resembling in its action the oil of absinthe, but less powerful.

The *dose* of the powdered leaves is from twenty to sixty grains (1.3–3.9 Gm.). *Dose*, of the infusion (one oz. in one pint of boiling water), two fluidounces (60 mils).

Although the *Salvia* officinalis was the only species of this genus which was recognized by the U. S. P. VIII, many other species share the feeble medicinal properties of sage. *S. pratensis* L., *S. Æthiopis* L., *S. glutinosa* L., and *S. Sclarea* L., or *clarry*, have been officially recognized in Europe, but are less agreeable than is *S. officinalis* and are not much used; the leaves of *S. Sclarea* are said to be introduced into wine in order to impart to it a muscatel taste. The infusion of the *Rocky Mountain sage*, probably *S. lanceolata* Willd., is affirmed by A. Comstock (*T. G.*, 1887, 660) to be valuable as a diaphoretic in *malarial* and *rheumatic fevers*, taken in the form of hot infusion, and when cold to be distinctly tonic and astringent. The *dose* of fluidextract is half a fluidrachm (1.8 mils).

The seeds of various sages contain enough farinaceous and mucilaginous material to make them useful as food. In the Western United States the

ordinary sages of the plains are highly esteemed for fattening cattle, which eat their ripened tops freely (these sages must be distinguished from the so-called "sage brushes" of the West, which belong to the genus *Artemisia*). *Chia* is the seeds of one or more species of *salvia* largely used in Mexico and Southern Arizona by the natives as food. It is affirmed that the variety known as *Chia pinoli* is yielded by *S. columbaria* (see *Report U. S. Geogr. Surveys, 100th Merid.*, vol. vi, 48). *S. Chia* was described in the Farmacopea Mexicana as a new species, yielding *chia*, but Mariano Báscena affirms (*La Naturaleza*, 1881) that the common chia-yielding sage of Mexico is *S. polystachya* Ort., while *Chia azul* is yielded by *S. patens* Cav. Guibourt is probably in error in ascribing chia to *S. hispanica* L. The chia seeds are used not only when crushed as food and for the making of mucilaginous poultices, but also for the preparation of a mucilaginous drink, prepared by adding a teaspoonful of the seed to a tumblerful of cold water, allowing it to stand for half an hour, sweetening and flavoring to taste. Chia seeds are described as follows: "The seed is oblong-ovate, somewhat flattish, from 1 to 8 mm. in length, at one end there is a small, dark line, forming a slight projection, which is the microphyle of the seed, and this, when exposed to moisture, opens in a star-shaped or scalloped manner, emitting the growing embryo. The seed is smooth and glossy, and is surrounded by a transparent epithelium, swelling very largely when in water. The testa is darkish-gray, striated with dark brown lines, running diagonally, and dotted, forming a very beautiful variegated surface; when pressed or crushed under a spatula it bursts at the hilum, exposing the cotyledons and the oil cells, leaving an oily stain upon paper. Internally the testa is dark, grayish-brown, perfectly smooth, glossy, and devoid of the external variegations or striæ. It contains the embryo, with the radical pointing towards the hilum, and a white, mucilaginous substance much resembling unrendered fat." (*A. J. P.*, May, 1882, 227–229.) The European species, *Salvia verticillata* L., *S. Verbenaca* L., *S. horminum* L. and *S. viridis* L., all indigenous to Central or Southern Europe, are also noted for the mucilaginous character of their seeds, and have on this account been employed to remove foreign substances from the eye. *S. Verbenaca* is sparingly naturalized in waste places in the Middle and Southern States.

Sago. *Sagou*, Fr. *Sago*, G., It. *Sagu*, Sp.—Under this name the U. S. P. formerly recognized the starch obtained from the *sago* palms. Numerous trees, inhabiting the islands and coasts of the Indian Ocean, contain a farinaceous pith from which is extracted the starch in enormous quantities. In India and the East Indies it is obtained from several palms, viz.: *Metroxylon Rumphii* Mart. and *M. lœve* Mart.

The fruit of the *Cycas circinalis*, according to J. van Donjen, contains a poisonous glucoside, *pakoëine*. (*P. J.*, May, 1903.)

According to H. von Rosenberg (*Proc. A. Ph. A.*, xxvii, 140), pith cells of these palms consist mostly of starch when the large leaves have fallen off and the flowers are just taking their place. At this time the tree is felled, and the trunk cut into billets six or seven feet long, which are split in order to facilitate the extraction of the pith. This is obtained in the state of a coarse powder, which is mixed with water in a trough having a sieve at the end. The water, loaded with farina, passes through the sieve, and is received in convenient vessels, where it is allowed to stand till the insoluble matter has subsided. It is then strained off, and the farina which is left may be dried into a kind of meal or molded into whatever shape may be desired. For the consumption of the natives it is usually formed into cakes of various sizes, which are dried, and extensively sold in the islands. The commercial "Pearl" sago is prepared by forming the meal into a paste with water, and rubbing it into grains. It is produced in the greatest abundance in the Moluccas, but of the finest quality on the eastern coast of Sumatra. The Chinese of Malacca refine it so as to give the grains a fine pearly luster. Malcolm states that it is also refined in large quantities at Singapore.

Pearl sago is that which is now generally used. It is in small grains, about the size of a pin head, hard, whitish, of a light brown color, in some instances translucent, inodorous, and with little taste. It may be rendered perfectly white by a solution of chlorinated lime. *Common sago* is in larger and browner grains, of more unequal size, of a duller aspect, and frequently mixed with more or less of a dirty looking powder.

An average palm about fifteen years old will yield from 300 to 400 kg. of sago starch.

Sago meal is imported into England from the East Indies. It is in the form of a fine amylaceous powder, of a whitish color, with a yellowish or reddish tint, and of somewhat musty odor.

Sago starch grains are oval or ovate and often truncated. As the article of commerce is partially cooked the grains are more or less altered. The individual grains usually show a large central area around which are the narrow, distinct altered lamellæ which are sometimes traversed by radiating fissures. The starch grains vary from 0.015 to 0.080 mm. in length. When examined by polarized light the grains show a distinct cross. At one time sago flour showed considerable amounts of stone cells, hairs and calcium oxalate crystals, but as the product is more highly refined in recent years, these impurities have been eliminated.

Common sago is insoluble in cold water, but by long boiling unites with that liquid, becoming at first soft and transparent, and ultimately forming a gelatinous solution. Pearl sago is partially dissolved by cold water, probably owing to the heat used in its preparation. Chemically considered, it is a very pure natural starch, as the nitrogenous matter rarely amounts to more than one per cent., and the ash to one-half per cent., the remainder being starch and moisture.

Potato starch is sometimes prepared so as to resemble bleached pearl sago, for which it is sold. But, when examined under the microscope, it exhibits larger granules, which are also more regularly oval or ovate, smoother, less broken, and more distinctly marked with lamellæ than are those of sago, and the hilum often cracks with two slightly diverging slits. Imitation sago is now made in the United States from various kinds of starch.

Sago is used exclusively as an easily digestible, non-irritating food. It is given in the liquid state, and in its preparation care should be taken to boil it long in water, and stir it diligently, in order that the grains may be thoroughly dissolved. Should any portion remain undissolved, it should be separated by straining. A tablespoonful to the pint of water is usually sufficient.

Sajodin. *N. N. R.* 1917. *Calcium mono-iodobehenate.* $(C_{22}H_{42}O_2I)_2Ca$.—This is prepared by treating erucic acid with hydriodic acid, which

yields monoiodobehenic acid. The combination of the latter with calcium, known as *sajodin*, is a white, odorless, tasteless powder containing 26 per cent. iodine. When heated it evolves iodine vapors and the residue, when dissolved and diluted hydrochloric acid with ammonium hydrate and ammonium oxalate added, will give a precipitate of calcium oxalate.

Because the salts of the fatty acids are not decomposed in the stomach this preparation passes uninjured into the intestinal canal and hence causes no irritation of the stomach. It is also claimed for it that when used for long periods of time it is much less liable to give rise to that disturbance of nutrition generally spoken of as iodism, but the claim at one time made for it that it was entirely free from the danger of unpleasant secondary actions has been shown by Kuttelwascher (*Pr. M. W.*, 1907) and others not to be true, although it appears to be better borne than the alkaline iodides. It seems also that it is somewhat more slowly absorbed than the ordinary iodides, probably because it is necessary to be broken up before its absorption. Delayed elimination which has been reported is probably due to the fact that it is absorbed more gradually than the alkaline iodides. There is abundant evidence that it is capable of replacing therapeutically the official forms of iodine and it has been widely used in all those conditions in which iodine is of service. The ordinary *dose* is from eight to fifteen grains (0.5–1.0 Gm.) three times a day, best given in the form of a powder which may be enclosed in gelatine capsules. It should not be administered in the form of pill or tablet.

Salacetol. *Salicyl-acetol. Salantol.* $C_6H_4(OH)CO.OCH_2CO.CH_3$.—A synthetic product, the ester of salicylic acid and acetylcarbinol, introduced as a substitute for salol, to avoid the elimination of phenol in the system. Crystallizes out of alcohol in white or pinkish needles, fusing at 71° C. (159.8° F.), slightly soluble in cold water and alcohol, readily soluble in ether, chloroform, and petroleum benzin. It may be used when salol is indicated, in *doses* of from thirty to forty-five grains (2.0–3.0 Gm.).

Salamander Alkaloids.—*Salamander maculosa*, and probably other newts, produce a poisonous secretion from the skin, from which Hoppe-Seyler and Zalesky separated an active body, *salamandarine*. E. S. Faust (*A. E. P. P.*, xliii) has secured crystalline salts from this body which produce in the lower animals restlessness, excited reflex activity, and convulsions ending in total paralysis. A second alkaloid, *salamandaridine*, was also separated by Faust.

Salen.—This preparation is a mixture of methyl and ethyl glycolic esters of salicylic acid. At ordinary temperatures it is a liquid, which congeals at 5° to 10° C. (41°–50° F.). It is readily soluble in alcohol, ether, castor oil and benzol, but insoluble in olive oil. It is used altogether for external applications, either full strength or diluted with its solvents.

Salep. *Tubera Salep*, P. G. *Salep*, Fr., G.—This name is given to the dried tubers of numerous species of the genus *Orchis*, and other allied genera of the *Orchidaceæ*. At present the *salep* of European commerce is prepared chiefly in the Levant, but to some extent in Germany and other parts of Europe. The German salep is said to be more translucent than the Levant.

Salep is in small, oval, irregular, ovoid or oblong tubers, rarely palmate, hard, horny, semitransparent, of a yellowish color, a feeble odor, and a mild mucilaginous taste. It is sometimes kept in the state of powder. In composition and relation to water it is closely analogous to tragacanth, consisting of a substance insoluble but swelling up in cold water (*bassorin*), of another in much smaller proportion, soluble in cold water, and of minute quantities of saline matters. It also occasionally contains a little starch. It is highly nutritive, and may be employed for the same purposes as tapioca, sago, etc. Its medieval and Oriental reputation as an aphrodisiac is unfounded. On account of its hardness, salep, in its ordinary state, is of difficult pulverization; but the difficulty is removed by macerating it in cold water until it becomes soft, and then rapidly drying it. *Royal salep*, said to be much used as a food in Afghanistan, has been identified by J. E. T. Aitchison as the product of *Allium Macleanii* Baker. (Fam. *Liliaceæ*.) (*P. J.*, Sept., 1889.)

E. Reeb stated that salep possesses, like diastase, the property of coagulating milk, which he attributes to *erythrodextrin*, but finds that this body, in distinction from diastase, will retain its coagulating property even after heating it to 100° C. (212° F.). (*Journ. der Pharm. v. Elsass-Lothringen*, 1912, No. 8.)

Sal-ethyl. *N. N. R.* 1917. *Ethyl-Salicylate.*—This proprietary ester is used after the manner of, and for the same purposes as, methyl salicylate. It is a colorless volatile fluid of pleasant odor and taste. Sp. gr. 1.184 and boiling at 231.5° C. (449° F.). The *dose* is five to fifteen minims (0.3–1 mil).

Salhypnone. $C_6H_4O(COC_6H_5)COOCH_3$.—A benzoyl-methyl-salicylic ester which occurs in colorless needles melting at 113° C. (235.4° F.), insoluble in water and sparingly soluble in alcohol and ether. It is a mild antiseptic.

Salibromin. $C_6H_2Br_2OH.COOHCH_3$. *Dibrom-salicylicmethyl Ester.*—This forms a white crystalline powder soluble in alkalies. It has been proposed as an antiseptic and antirheumatic in *doses* of eight grains (0.5 Gm.), four or five times daily.

Salicylamide. *Salamid.* $C_6H_4\begin{cases}OH\\CONH_2\end{cases}$.—This compound is prepared by the action of concentrated ammonia upon methyl salicylate. When purified, it occurs in colorless, thin, transparent plates, melting at 138° C. (280.4° F.), soluble in alcohol, ether, chloroform, and two hundred parts of water. W. B. Nesbitt finds that this substance, when given in toxic dose, paralyzes the motor nerves and centers, also the muscles, and has but little effect upon blood pressure. He believes that it is a safer remedy than salicylic acid, and has the advantage of greater solubility and more prompt action in smaller dose. Also, that it has analgesic and antipyretic properties which correspond. It may be given in *doses* of three grains (0.2 Gm.). The highest amount used was fifteen grains (1.0 Gm.), taken in nine hours. (*T. G.*, Oct., 1891.)

Salicyl Resorcin Ketone. *Tri-oxy-benzo-phenone.* $C_{13}H_{10}O_4$.—A reddish-white crystalline powder, but sparingly soluble in water. It has been suggested as an intestinal antiseptic and as an antirheumatic. The *dose* is five to fifteen grains (0.32–1.0 Gm.).

Salifebrin. *Salicylanilide.*—An antipyretic, made by heating together salicylic acid and acetanilide in molecular proportions. It is a color-

less permanent powder, insoluble in water, freely soluble in alcohol.

Saligallol. *Pyrogallol Di-salicylate.*—A resinous solid, soluble in two parts of acetone and fifteen parts of chloroform. Its solution in acetone has been used as an external application in skin diseases.

Saligenin, *Ortho-oxybenzyl alcohol,* $C_6H_4.OH.CH_2OH$, is the decomposition product of the glucoside *salicin.* Under the name of *antiarthrin,* a substance has been introduced into commerce which is said to be a combination product between *saligenin* and tannin. It readily undergoes decomposition. It has been used in chronic *rheumatism* and *gout* in *doses* of eight to twenty grains (0.5–1.2 Gm.) four to six times a day.

Salimenthol.—*Samol, Salicylic Ester of Menthol,* $C_6H_4(OH)COO.C_{10}H_{19}$, is an almost colorless fluid, insoluble in water, but miscible with alcohol, ether, chloroform and fatty oils in all proportions.

It is supposed to exercise the virtues of both of its constituents and is employed in various rheumatic and painful conditions by external application with the idea that it will act as a local anodyne by virtue of its menthol radical and being absorbed will exercise the analgesic effect of salicylic acid. It may be applied in the form of a 25 per cent. ointment. It has also been administered internally in *doses* of eight to fifteen drops (0.5–1.0 Gm.), generally enclosed in capsules.

Saliphen. *Saliphenin. Salicyl-p-phenetidin.* $C_6H_4(OC_2H_5)NH.C_6H_4(OH)CO$.—This substance is the product of a reaction between salicylic acid and phenetidin in the presence of phosphorus trichloride. It is in colorless crystals, which melt at 139.5° C. (283° F.); is insoluble in water, but soluble in boiling alcohol, acetone, ether, chloroform and glacial acetic acid. It possesses slight antifebrile properties.

Salipyrin. *N. N. R.* 1917. *Antipyrine Salicylate. Salazolon.* $C_{11}H_{12}N_2O.C_7H_6O_3$.—Prepared by the action of salicylic acid upon antipyrine, either at 100° C. (212° F.) or in solution. It occurs as a white, coarsely crystalline powder, odorless, with a somewhat sweetish taste. It is readily soluble in alcohol and in benzene, and crystallizes from the former in hexagonal tables with a melting point of 91.5° C. (196.7° F.). According to Guttmann and to Kollmann (*Internat. Klin. Rundsch.,* Sept., 1890; also *M. M. W.,* Nov., 1890), it is an active antipyretic and antirheumatic, which rarely produces toxic symptoms, although an eruption resembling that caused by antipyrine has been noted. Kollmann states that it sometimes causes vomiting, and the daily *dose* should not exceed forty-five grains (3.0 Gm.), and always be less than this in the beginning, as some individuals are intolerant of it. *Salipyrin* has been used to a considerable extent in all forms of *rheumatic diseases,* in *influenza,* in various *fevers,* in *migraine,* and in the whole class of diseases in which its component constituents have been found to be useful; also locally in *coryza.* Salipyrin has been very highly praised by Beuttner as a sedative antihemorrhagic remedy, in all forms of *metrorrhagia* not dependent upon severe organic disease, in threatened *abortion,* and in *dysmenorrhea.* The usual *dose* is from seven to fifteen grains (0.45–1.0 Gm.), in capsule or tablet, repeated every three or four hours, until not over 45 grains (3 Gm.) have been taken.

Salit. *Salicylic Ester of Borneol.* $C_{10}H_{17}O.CO.C_6H_4.OH$.—It occurs as an oily fluid, insoluble in water, but readily soluble in alcohol, ether, and oils. It is incompatible with alkalies and alkaline salts.

Salit is employed for the purpose of the endermic administration of salicylic acid in *neuralgia,* and acute and chronic *rheumatic disorders.* In a few instances its application has given rise to a slight irritation of the skin. It should generally be diluted with equal portions of olive oil, and one-half to one teaspoonful of the mixture applied with friction or by painting over the infected part and covering with an impermeable dressing.

Salitannol. $C_{14}H_{10}O_7$.—A condensation product of salicylic and gallic acids; it is a colorless powder, insoluble in water, ether, chloroform, and benzene, slightly soluble in alcohol, soluble in solutions of caustic alkalies. It is used as a surgical antiseptic.

Salithymol. *Thymol Ester of Salicylic Acid.* $C_6H_3(CH_3)(C_3H_7)O.COC_6H_4(OH)$.—This salt is prepared by acting on molecular quantities of sodium salicylate and thymol sodium with phosphorus trichloride. It is a colorless crystalline powder, of sweet taste, insoluble in water, very soluble in alcohol. It is used as an antiseptic. *Dose,* from fifteen to thirty grains (1–2 Gm.).

Salix. U. S. 1880.—*Willow-bark. Weidewinde,* G. *Ecorce de Saule,* Fr. Most of the species of the large genus *Salix* are possessed of similar medicinal properties. (For elaborate study of various willow barks see *Wellcome Chemical Research Laboratory Report,* No. 39.) *S. fragilis* L. or Crack Willow, which has been introduced into this country from Europe, is said by Sir James Smith to be the most valuable species. *S. purpurea* L., a European species, is stated by Lindley to be the most bitter, and *S. pentandra* L. is preferred by Nees von Esenbeck. Many native species are in all probability equally active with the foreign.

Salix alba L., the species formerly recognized by the U. S. Pharmacopœia, is the common European or *white willow.* It has sparingly escaped from cultivation, growing from New Brunswick and Ontario southward to Pennsylvania. It is a large tree with a rough grayish bark, the twigs being brittle at the base, and in this respect somewhat resembling *S. fragilis.* The leaves are pubescent on both surfaces and finely serrulate. It hybridizes with other species of *Salix.* It flowers in April and May, and the bark is easily separable throughout the summer. That obtained from the branches rolls up when dried into the form of a quill, from 0.5 to 1 mm. thick, has a brown, more or less finely warty periderm, is flexible, fibrous, and of difficult pulverization. The inner surface is brownish-white, and smooth, separating in thin layers. Willow bark has a feebly aromatic odor and a peculiar bitter astringent taste. It yields its active properties to water, with which it forms a reddish-brown decoction. Pelletier and Caventou found among its ingredients, tannin, resin, a bitter yellow coloring matter, a green fatty matter, gum, wax, lignin, and an organic acid combined with magnesia. The proportion of tannin is so considerable that the bark has been used for tanning leather. The characteristic constituent of all species of willow, however, is *salicin.* (See *Salicinum,* p. 0000.) Robert W. Beck (*A. J. P.,* 1891, 581) has determined the relative percentages of salicin and tannin as follows:

	Salicin.	Tannin.
Leaves of *S. lucida* Muhl	0.30 per cent.	6.48 per cent.
Bark of *S. lucida* Muhl	1.09 " "	3.58 " "
Bark of *S. alba* L.	0.56 " "	4.26 " "
Bark of *S. nigra* Marsh	0.73 " "	3.29 " "

Jowett and Potter made an examination of thirty-three samples of willow and poplar, and found in but one (*Salix discolor* Muhl.) the related glucoside *salinigrin*, which Jowett had previously discovered in an unknown sample of willow bark. This compound has the formula $C_{13}H_{16}O_7$, and on hydrolysis yields glucose and meta-hydroxybenzaldehyde. (*Wellcome Chem. Research Laboratory Report*, No. 28.) The bark of the willow is feebly tonic, but it is at present never employed in regular medicine.

Salix nigra Marsh. *Black Willow.*—This is a tree with a dark brown bark, and is noted for its rapid distribution along streams into which its brittle twigs fall, which strike root, forming new plants. It hybridizes with *Salix alba*. The younger Michaux states that this is a strong bitter, and according to various eclectic practitioners its green aments or floral buds are a very active sexual depressant, useful in *spermatorrhœa*, in all forms of *sexual excitement*, and in the nervous disturbances of the menstrual period. From twenty to thirty minims (1.3–1.8 mils) of the fluidextract are to be given four times a day.

The *Pussy Willow* (*Salix discolor* Muhl.) is a shrub growing in swamps and on moist hillsides of the northern United States. It is well known because of its silky downy catkins which appear in early spring before the leaves.

Salocoll. *Phenocoll Salicylate.* $C_6H_4(OC_2H_5)NH.COCH_2.NH_2C_7H_6O_3$.—This substance forms fine white crystalline needles of sweet taste and soluble in hot water. It combines the properties of phenocoll and salicylic acid, being used in *rheumatic affections* in *doses* of nine to fifteen grains (0.6–1.0 Gm.) several times daily.

Salocreol is a preparation containing an ester of the various phenols of beechwood tar. It occurs as a fluid of neutral reaction, oily consistence, brownish color, and is almost completely odorless. It is almost insoluble in water, easily soluble in the various alcohols, ether, or chloroform. It is saponified by the alkalies and alcohols, and on prolonged exposure also by glycerin. In saponified solutions the addition of a trace of ferric chloride produces the violet colors characteristic of phenol and salicylic acid in neutral solutions. It is affirmed that it is readily absorbed by the skin and does not irritate it or stain it permanently. It is used as a local application in *erysipelas* and *rheumatism*. From one to two fluidrachms (3.9–7.5 mils) may be applied at a dose.

Salophen. *N. N. R.* 1917.—*Acetylparaminophenol Salicylate,* $C_6H_4\begin{cases}OH\\COOC_6H_4.NH(C_2H_3O)\end{cases}$, is formed by the combination of salicylic acid with acetylparamidophenol, and contains 51 per cent. of salicylic acid. It forms small white crystalline scales melting at 187° C. (368.6° F.), and is almost insoluble in cold water; moderately soluble in alcohol and ether. In warm alkaline solution it undergoes decomposition into salicylic acid and acetylparamidophenol. According to Siebel (*Th. M.*, Jan., 1892), this reaction takes place in the intestines. It has been used by various clinicians in all forms of *rheumatic diseases* and is undoubtedly effective, though less certain in its action than are the simple salicylates. It is also used to some extent as an analgesic in the pains of nervous diseases, in *pruritus*, and also as an intestinal antiseptic. It should not be confounded with Saliphen.

Dose, ten to fifteen grains (0.65–1.0 Gm.); not more than seventy-five grains should be given daily.

Saloquinine. *N. N. R.* 1917. *Salochinin.* $C_6H_4.OH.CO.O.C_{20}H_{23}N_2O$.—*Quinine ester of salicylic acid* occurs in colorless crystals, insoluble in water, freely soluble in alcohol and ether, fusing at 130° C. (266° F.). Acids or strongly acid salts decompose it, splitting it up into its constituents. It is tasteless and is said not to disturb the digestion or to cause tinnitus aurium, although it is very slowly absorbed. It is said to contain 70 per cent. of quinine, and has been used successfully as an antiperiodic, but is reputed to be of special value in the treatment of malarial and other *neuralgias*, also in fulgurant pains, and has also been highly commended in *typhoid* and other *fevers* as an antipyretic. If in a fever it be administered directly after the cold bath, it begins to powerfully impress the system about the time the effect of the immersion is going off. It may be given in the single *dose* of from fifteen to thirty grains (1–2 Gm.), repeated within twenty-four hours in bad cases of *rheumatic affections*.

Saloquinine Salicylate. *Rheumatin.* $C_6H_4.OH.CO.O(C_{20}H_{23}ON_2).C_6H_4OH.COOH$.—A white, tasteless powder. Slightly soluble in water, readily in chloroform and ether. It is used in *neuralgia*, *rheumatism*, etc., in fifteen-grain (1 Gm.) *doses*.

Salubrol. *Tetra-bromo-methylene-di-antipyrine.* $C_{23}H_{24}O_2N_4Br_4$.—An inodorous orange-yellow powder, made by the action of bromine on methylantipyrine. It is non-poisonous, and is used as a local hemostatic and antiseptic and as a substitute for iodoform.

Salvarsan. *N. N. R.* 1917. *Arsen-phenol-amine-hydrochloride. Arsenobenzol.* "606." $HCl.NH_2.OH.C_6H_3.As:As.C_6H_3OH.NH_2HCl + 2H_2O$.—It is a yellow crystalline hygroscopic powder, easily decomposed in the air. It dissolves in water, yielding a solution with a slightly acid reaction. In administering it hypodermically, this acidity must be exactly neutralized. This is accomplished by the cautious addition of normal volumetric sodium hydroxide solution.

Salvarsan was introduced into medicine as the result of a long series of experiments by Professor Ehrlich. The plan of his research was to obtain some arsenical in which the element would be so firmly bound up that it could not be split off by the human organism and therefore would be nontoxic to man but which would retain its destructive action on protozoal parasites, especially the group known as *spirilli* to which belong the germs causing relapsing fever, sleeping sickness, and syphilis. While it seems demonstrated that a certain proportion of the salvarsan will be decomposed in the human body with the liberation of inorganic arsenic, to what extent this breaking up of the molecule takes place is as yet uncertain. Luithlen (*Z. P. C.*, 1913, xiii) maintains that the toxic symptoms sometimes caused by salvarsan are due to the action of the molecule as a whole and not to any arsenic which may be liberated. On the other hand, Hoke and Rihl (*Z. E. P. T.*, 1911, ix, p. 332) find that the toxic effects of salvarsan are precisely the same as those of arsenic poisoning. In whichever way it acts there is no doubt that in large dose it is poisonous and that, even in quantities not exceeding the ordinary therapeutic doses, it occasionally produces serious poisoning. Corlett (*J. A. M. A.*, 1913, lxi) has collected the reports of 126 deaths following its use and estimates the mortality as 1 in 18,000 injections.

As regards the curative powers of salvarsan the greatest interest has centered around its use in *syphilis*. While there is no room for doubt as to its beneficial effects in this disease it cannot be

considered as a certain cure for all cases. Indeed, Pusey maintains that it "Does not cure syphilis in any more cases than mercury does." (*J. A. M. A.*, October 5, 1912.) The general consensus is, however, that at least in the early stages its effects are not only more prompt than those of mercury, but also more certain. Craig (*A. In. M.*, 1911), in 225 cases, found a temporary disappearance of the Wassermann reaction in 70 per cent. and a permanent disappearance in about 55 per cent. It should be noted that the original idea that a single dose of salvarsan was sufficient has been entirely abandoned, and even its most ardent advocates administer from three to four doses. In the tertiary manifestations of *syphilis*, especially those involving the nervous system, the action of salvarsan has been less satisfactory, but recently good results have been claimed for the intraspinal injection of the drug in *locomotor ataxia*.

Salvarsan is useful in a large number of other diseases besides *syphilis*, especially those that are due to pathogenic protozoa, such as *relapsing fever, frambesia* and *filiariasis*. Good results have also been reported in *malaria, dysentery, pernicious anemia*, etc.

Salvarsan is usually administered either by intramuscular or by intravenous injection. It seems to be demonstrated that the sodium salt is less liable to produce unpleasant sequelæ than the acid preparation, and it is therefore preferable to neutralize the salvarsan before its injection. When sufficient alkali is added to exactly neutralize the salvarsan it is no longer soluble in water, but the resulting compound becomes dissolved by the further addition of caustic alkali. For practical purposes the salvarsan may be dissolved in a little water and a normal solution of sodium hydroxide added until the precipitate which is at first formed is redissolved, and to this may then be added as large an amount of physiological salt solution as a diluent as may be deemed necessary. The technic of the injection is so complex that it should be undertaken only by those who have had practical experience in its application. The doses which are used to-day are much larger than those employed when the drug was first introduced. From three to nine grains (0.2–0.6 Gm.) may be given for the first *dose*. The injections may be repeated at intervals of one or two weeks, the dose being increased or not, according to the circumstances in the individual case.

Under the name of *neo-salvarsan* has been introduced a compound of salvarsan with formaldehyde sulphoxylate. It contains approximately two-thirds as much arsenic as salvarsan. It is an orange-yellow powder with a characteristic odor, even more unstable in the air than is salvarsan. It is freely soluble in water. It was introduced as a substitute for salvarsan because its solutions do not require neutralization before injection. The dose of neo-salvarsan is about half again as large as that of the older preparation.

Salvarsan is contra-indicated in disorders of the circulatory apparatus, advanced degeneration of the central nervous system, certain forms of *bronchitis*, and severe cachexia of non-syphilitic origin.

The European War having interfered with the commerce in salvarsan, a number of preparations purporting to be chemically identical with salvarsan have been introduced under various names as *kharsivan* and *arsenobenzol*. *Neokharsivan* and *novarseno-benzol* are supposed to correspond with neo-salvarsan.

Samandera Bark.—This is the inner bark of *Samandera indica* Gärtn., a tree belonging to the family of *Simarubaceæ*, growing in Ceylon and the East Indies. It is intensely bitter, and probably contains quassin. For further particulars, see *P. J.*, 1872, 541.

Sanatol.—This is a disinfectant solution claimed to be an aqueous solution of the sulphonic acids of crude phenol with about 60 per cent. water and to possess powerful disinfecting properties. When analyzed by the Vienna City Laboratories it was found to be a solution of naphthalin and concentrated sulphuric acid.

Sandal Wood. *Santalum Album. White Sandal Wood.*—"The heart wood of *Santalum album* Linné (Fam. *Santalaceæ*)." *N. F. IV.*

White *sandal wood* was introduced into the N. F. IV to serve as an ingredient in *tincture of saw palmetto and santal* of the National Formulary. It is described as follows:

"In billets, pieces or chips of varying shapes and sizes, heavy, hard but splitting easily, color light yellow; transverse sections yellow to light reddish-brown, with alternating light and dark concentric zones nearly equal in diameter, with numerous pores and traversed by many very narrow medullary rays.

"When examined under the microscope, sections show the medullary rays from two to four rows wide, the cells thick-walled and radially marked; the wood wedges consisting largely of wood fibers with pointed ends, large parenchyma and thick-walled secretion vessels and cells containing single crystals of calcium oxalate; the oil in globules adhering to the walls of the ducts and parenchyma cells and especially rich in the medullary cells. Odor characteristic, aromatic, persistent; taste peculiar, strongly aromatic.

"Sandal Wood yields not more than 8 per cent. of ash." *N. F. IV.* For further information on sandalwood see *Oleum Santali*, Part I. It owes its therapeutic virtue entirely to the volatile oil it contains.

Sandarac. *Sandaraca. Gum Juniper. Sandaraque*, Fr. *Sandarak*, G.—A resinous substance obtained from the *Callitris quadrivalvis* Vent. (*Thuja articulata* Vahl.), an evergreen tree (fam. *Pinaceæ*) growing in the mountains of northwestern Africa.

Sandarac is a resinous exudation which occurs as a natural secretion in schizo-lysigenous reservoirs in the bark. It exudes naturally, but an increase in yield is obtained by cutting through the bark. The exuding resin hardens and is collected. It is sent by the natives to Mogador, Casablanca and Nazagan. From these points it is shipped to London, Trieste, Marseilles and Hamburg. It occurs in small, irregular, roundish oblong grains or tears, of a pale yellow color, sometimes inclining to brown, more or less transparent, dry and brittle, breaking into powder under the teeth, of a faint, agreeable odor increased by warmth, and of a resinous, slightly acrid taste. It melts with heat, diffusing a strong balsamic odor, and easily inflames. It is almost entirely soluble in ordinary alcohol, and entirely so in that liquid when anhydrous, and in ether. Heated oil of turpentine also dissolves the greater part of it, but very slowly. According to Unverdorben, it consists of three resins, varying in their relations to alcohol, ether, and oil of turpentine. The *sandaracin* of Geise, which remains after sandarac has been exposed to the action of ordinary alcohol, is a mixture of two of these resins. Tschirch (*Harze und Harzbehälter*, p. 276) has isolated and de-

scribed an acid, *sandaracolic acid*, $C_{44}H_{64}O_4(OH)COOH$, making up 85 per cent. of the natural resin and *callitrolic acid*, $C_{64}H_{82}O_5(OH)COOH$, of which 10 per cent. is present. In Australia and Tasmania Callītris trees grow in vast numbers, and produce a sandarac which is almost colorless, having highly refractive power, and a pleasant aromatic odor, becoming dark by age, and sometimes assuming a superficial mealiness. This Australian sandarac softens easily, but does not melt in boiling water, is gritty to the touch, and can scarcely be distinguished from the African drug. (*P. J.*, Jan., 1890.) For an elaborate description of Australian sandarach, see also *A. J. P.*, 1896, 215. Sandarach was formerly given internally, and entered into the composition of various ointments and plasters. At present it is used chiefly as a varnish and as incense; its powder, termed *pounce*, is rubbed upon paper to prevent ink from spreading after letters have been scratched out. It is sometimes adulterated with mastic, rosin and dammar. A false sandarach has been described by R. Haneke. It resembled the real article, being lemon-yellow in color, transparent, and the tears elongated and rounded at the tips. When chewed it broke into fine powder and stuck to the teeth, while it softened on the water bath and flowed together into a resinous mass. Examination showed it to consist largely of colophony. (*O. Z.*, liv.)

Sanicula. *Sanicula marylandica* L. *Sanicle*, Fr. *Sanikel*, G.—The root of this indigenous umbellifer is popularly known in some parts of the country by the name of *black snake-root*. It is fibrous and of an aromatic taste, and, according to C. I. Houck (*A. J. P.*, vol. xiv, 463), contains a volatile oil and a resin. It has been used in *intermittent fever*, and also in *chorea* by Zabriskie. *Dose* of powder to children eight years old, half a drachm (2.0 Gm.) three times a day. (*Am. J. M. S.*, n. s., xii, 374.)

Sanitas.—This name is given to a fluid prepared by forcing air through a mixture of Russian turpentine oil and water, heated at 60° C. (140° F.) for a period ranging from 4 to 12 days. Among the various oxidation products is a soluble camphor ($C_{10}H_{16}O_3$), remaining dissolved in the oil, also a peroxide. It is used as an application for *burns*, *sores*, and *skin diseases*, and as a general disinfectant for sick rooms.

Sanochinol. *Sanschinol.*—This quinine compound is asserted to be the product of the action of ozone on a solution containing 4 per cent. of quinine hydrochloride. It forms a yellowish-brown solution, and is recommended for administration in the treatment of *malarial fevers* and *tuberculosis*.

Sanoform. *Di-iodo-methyl Salicylate.*

$C_6H_2\begin{cases}\diagup COOCH_3\\ —OH\\ \diagdown I_2\end{cases}$.—This substance is obtained by the action of iodine on methyl salicylate. It is a crystalline, colorless, odorless, and tasteless powder, permanent in the light and air, and melting at 110° C. (230° F.), but may be heated up to 200° C. (392° F.) without decomposing. It is soluble in 200 parts of cold or 10 parts of hot alcohol, and readily in ether, chloroform, benzene, and carbon disulphide, but almost insoluble in water or glycerin. It contains 62.7 per cent. of iodine. It forms with caustic alkalies, salts which are sparingly soluble in water.

Sanoform, first introduced as a substitute for iodoform by A. Arnheim, would appear to afford an efficient antiseptic dressing for wounds. As it remains unchanged at high temperatures, it is readily sterilized, while its odorlessness gives it a great advantage over iodoform. Its absorption is extremely slow, as it does not appear in the urine after having been administered hypodermically until twenty-four hours have elapsed, and does not entirely disappear until after fourteen days. It is seemingly, therefore, less poisonous than iodoform. It may be used as a dusting powder or in the manufacture of a 10 per cent. gauze which can be sterilized by heating; or a 1 per cent. solution in collodion, or a 10 per cent. ointment may be employed. It has been employed with satisfaction in ophthalmic surgery by Radziejewski and by Jacobsohn.

Santalol Formaldehyde.—Formic aldehyde in combination with oil of sandalwood and some inorganic acid is the source of this product. It is a balsamic yellow fluid, which in the presence of water breaks up into its components. It is employed in the treatment of inflammatory conditions of the bladder and kidneys.

Santolina.—A composite plant, commonly called *Holy herb, Heiligenpflanzen, Cypress herb, Cypressenkraut* (*Santolina Chamæcyparissus* L.), is stated to have long been used popularly against the *round worm* in Scotland. It has been analyzed by T. Maben (*P. J.*, xvi, 301), who finds in it a volatile oil and a considerable percentage of resin, with a bitter principle, which he believes to be an alkaloid and the active principle of the drug. The decoction of the plant may be made by boiling half an ounce in a pint of water for half an hour, straining and making up to a pint. It is given in *doses* of five fluidounces (150 mils) to adults and half that quantity to children, repeated for four mornings, and then followed by a brisk cathartic.

Santonica. *U. S. VIII. Levant Wormseed. Turkestan, Aleppo, Alexandria*, or *European Wormseed. Santonici Semen. Semen Cinæ. Flores Artemisiæ. Semen Sanctum. Semen-contra Dalep. Semencine ou Barbotine*, Fr. Cod. *Flores Cinæ*, P. G. *Wurmsamen, Zitwersamen*, G. *Santonico*, It., Sp.—The dried unexpanded flowers of the *Artemisia Cina* Berg. (*A. pauciflora* (Ledebour) Weber) (Fam. *Compositæ*). This plant is a small, semi-shrubby perennial, from whose oblique, knotted rootstalks arise numerous leafy shoots and flowering stems. The glabrous and woody stems bear on their many branches numerous small (one inch long) bi- to multi-pinnatifid leaves, while the leaves of the flowering stems are very minute, the upper ones simple. The flower heads are small, numerous, one-tenth of an inch long, with from twelve to eighteen involucral scales, and from three to five flowers. The plant varies very greatly, and several species have been made out of its varieties. The plant grows in Persia and Turkestan and the flower-buds are collected in July and August. The Levant wormseed was officially described as "heads 2 to 4 Mm. long, oblong-ovoid, slightly flattened, obtuse, consisting of an involucre of about 12 to 18 closely imbricated, glandular scales with broad midribs, enclosing 4 to 5 rudimentary florets. *Santonica* has the appearance of a granular, yellowish-green or greenish-brown, somewhat glossy powder; odor strong, peculiar, somewhat camphoraceous; taste aromatic and bitter." *U. S. VIII.* Astolfi (*Ph. Ztg.*, 1893, 333) gives the following test for recognizing adulteration of santonica. 1 Gm. of the suspected drug is finely pulverized and then

agitated with 10 mils of absolute alcohol; the whole is heated to boiling, filtered, a piece of potassium hydroxide is added to the filtrate, which is then heated. If the drug is pure, the liquid will acquire a pronounced red color; if falsified, the color will be yellow; and if no santonica be present, the liquid will be colored but faintly, if at all.

Most of the wormseed of commerce comes from the steppes of the northern portion of Turkestan to the great Nizhni-Novgorod fair, whence it finds its way to Moscow and Western Europe. The export from this region has largely declined, because of the erection in Orenburg and Tschimkent of factories for the manufacture of santonin, which is now sent from there into commerce. The yearly consumption of santonin throughout the world is estimated at about twenty-five tons, and of this at least twelve tons are produced in the factories just spoken of. The santonin in the plants is said to reach its maximum proportion in July and August, and to disappear immediately after the flowering.

Attention was called by C. H. LaWall (*J. A. Ph. A.*, 1913, p. 596) to a variety of santonica that has appeared upon the market, which seems to be devoid of santonin or to contain not more than traces. He proposes a simple test which may be applied directly to the drug as a preliminary procedure and thus avoid the necessity of going through the long assay process if the sample is valueless: Place 5 Gm. of santonica (whole or ground) in a test tube, add 5 mils of spirit of nitrous ether and boil gently. No more color should be developed or not more than a slight greenish yellow color due to the solvent action of the spirit on the resins of the drug. Now add 10 drops of alcoholic solution of potassium hydroxide. In an active drug a rose red color is developed in direct proportion to the amount of santonin present.

Wormseed contains a volatile oil, but it owes its efficiency to *santonin.* (See *Santoninum.*) According to Merck, the mother liquors in the manufacture of santonin from the seeds of *Artemisia maritima* yield a crystalline principle, $C_{15}H_{18}O_4$, which has been named *artemisin.* It is freed from santonin by recrystallization from chloroform. It melts at 200° C. (392° F.), gradually turns yellow in the air, and is more readily soluble in water and in dilute alcohol than is santonin. It gives a fugitive carmine red color when heated with aqueous or alcoholic sodium hydroxide, and is apparently a *hydroxy-santonin.* (*P. J.*, 1896, 484.) *Dose*, of artemisin, one-six hundred and fortieth of a grain (0.0001 Gm.). The oil of santonica, according to Wallach (*Ann. Ch. Ph.*, ccxxv, 314; and ccxxvii, 277), consists chiefly of *cineol*, $C_{10}H_{18}O$, which is isomeric with borneol, and seems to be identical with the cajuputol of cajuput oil, together with some *dipentene.* Wormseed is rarely used in this country in substance. It is stated that artemisin is a powerful stimulant to the mucous membrane and muscles of the alimentary canal and that its addition to the simple bitters greatly increases their activity. *Dose*, of santonica, ten to thirty grains (0.65–2.0 Gm.). For a method of valuing santonica, by Dragendorff, see *Proc. A. Ph. A.*, xxvi, 229. For *Ehling's Process for Valuing Santonica*, see *U. S. D.*, 19th ed., page. 1085.

Santoninoxime. $C_{15}H_{18}O_2.N.OH$.—This substance was first prepared in 1889 by P. Guici (*Gazz. Chim.*, xix, 367) by digesting at nearly 80° C. (176° F.) for three days five parts of santonin, four parts of hydroxylamine hydrochloride, fifty parts of strong alcohol, and four parts of precipitated calcium carbonate. It crystallizes in white silky needles, melts at about 217° C. (422.6° F.), is very slightly soluble in hot water, and turns the plane of polarized light to the left. Coppola states that this substance is a safe and reliable substitute for santonin, to be given in *doses* about three times as large.

Santyl. *N. N. R.* 1917. $C_{15}H_{23}O.CO.C_6H_4OH$. —This preparation is the salicylic acid ester of santalol (the terpene alcohol of oil of sandalwood), occurring as a yellowish oil of pleasant balsamic odor and taste, having a specific gravity of 1.07 at 15° C. (59° F.), and boiling with decomposition at 121° to 126° C. (249.8°–258.8° F.). A number of authors have reported that *santyl* has distinct advantages over the oil of sandalwood and most of its compounds, especially in the treatment of *urethritis.* Its taste is less disagreeable than that of the oil; it is also apparently much less liable to disturb the stomach and some believe that it is more active as a disinfectant because of the salicylic acid constituent in its molecule. Kanitz (*Th. M.*, 1907) found that not only was it non-irritant to the alimentary tract or the kidneys, but that it contains a very marked power of alleviating the painful symptoms, and to an extent, to directly antagonize the urethral inflammation in *gonorrhea.* Menier (*B. K. W.*, 1907) has found the local application of santyl useful in *ozena.* Strassmann (*Derm. Cb.*, 1907, No. 6) has found it of much value in the treatment of *cystitis*, due to prostatic enlargement. The *dose* is fifteen to thirty minims (1–2 mils) three times a day given either in water or milk.

Sapindus.—Various tropical plants belonging to this genus of the *Sapindaceæ* contain saponin, and are largely used for cleaning purposes. The berries are commonly used, being called "*Soap berries.*" Thus, in India are employed the pulp of the fruit of *Sapindus Mukorossi* Gaertn., the capsules of *S. trifoliatus* L., and in South America the oil and seed vessels of *S. Saponaria* L. (*P. J.*, 1871, 585.) For the properties of saponin, see *Saponaria officinalis*, below. The fruits of *S. rarak* DC., according to O. May, contain saponin and a fixed oil. (*A. Pharm.*, 1906, 25.)

Sapium. *Sapium sebiferum* (L.) Roxb. *Chinese Tallow Tree. Tankawang Fat.*—This is a species of the family *Euphorbiaceæ*, cultivated in the Chinese provinces of Kiangse, Kiang-sou, and Chih-kiang for the sake of the fixed oil which covers the seeds, and is extracted by methods detailed in *A. J. P.*, 1872, 264. (See *P. J.*, June, 1872.) The "tallow" occurs in hard, brittle, opaque, white masses of about eighty pounds' weight. It consists chiefly of palmitin with a little stearin and is said to be nearly pure stearin. The oil is largely used for lighting purposes. The remnants of the nut are employed as fuel and as manure. (See also *P. J.*, 1883, 401, and 1887, 901.)

Saponaria. *Saponaria officinalis* L. *Soapwort. Bouncing Bet. Fuller's Herb. Sheep Weed. Saponaire. Savonnière*, Fr. *Seifenwurzel*, G. (Fam. *Caryophyllaceæ.*)—A perennial, herbaceous plant, having large rose-colored flowers, which are commonly double. It is common along roadsides and waste places in the United States. The rhizome and roots are employed. The rhizomes are cylindrical, from 5 to 12 cm. long and 5 to 12 mm. thick, outer surface being reddish-brown. The fracture is short and even. They are inodorous, and of a taste at first bitterish and slightly sweetish, afterwards somewhat pungent, continuing long,

and leaving a slight sense of numbness on the tongue. They impart to water the property of forming a lather when agitated, like a solution of soap, whence the name of the plant was derived. This property, as well as the medicinal virtues of the plant, resides in *saponin*, $C_{32}H_{54}O_{18}$. This principle constitutes, according to Bucholz, its discoverer, 34 per cent. of the dried root which contains also a considerable quantity of gum and a little bassorin, resin, and altered extractive, besides lignin and water. For description of *saponin*, see *Quillaja*. Saponin has been found in many other plants, among them some species of *Silene*, *Dianthus*, and *Lychnis*, in *Vaccaria vulgaris* Host., and in *Agrostemma Githago* L., all belonging to the fam. *Caryophyllaceæ*. (*J. P. C.*, 3e sér., x, 339; also *P. J.*, 1871, 585; *Australian Journ. Pharm.*, 1887.) Serious poisonings by the mixture of the seeds of *Agrostemma Githago* with wheat have been reported. (*D. M. W.*, 1903.) According to Augustine Henry, there are at least eleven species of trees whose products are used in China for washing purposes and probably contain saponin, which is also found to the extent of 10 per cent. in the seeds of the Chinese tea oil tree, and is left in such large proportion in the refuse after the extraction of the oil that the "tea seed cake" is used as a fish poison. (*Am. Drug.*, 1896.) In California the *Indian Soap Root, Chlorogallum pomeridianum* (Ker.) Kunth., is much used for washing clothes; it probably contains saponin. The fruits of various species of *Sapindus* are also rich in saponin and are used as detergents accordingly.

Saprol. *Disinfection Oil.*—A mixture of crude cresols, containing pyridine bases and hydrocarbons, used for disinfecting purposes. As it is inflammable, care should be exercised in its use.

Sarcocolla. *Sarcocolle*, Fr. *Fleischleimgummi*, *Fischleimgummi*, G.—A peculiar vegetable product, exuding spontaneously from *Penæa Sarcocolla* L. (now *P. fulcata* L.), and *P. mucronata* L. (Fam. *Penæaceæ*), small shrubs, growing at the Cape of Good Hope, in Ethiopia, Arabia, etc. *Sarcocolla* occurs in the form of small, roundish, irregular grains, somewhat spongy, sometimes agglutinated in masses, at times admixed with fine hairs, friable, opaque or semi-transparent, of a yellowish or brownish-red color, inodorous unless heated, when they have an agreeable odor, and of a peculiar, bitter, sweetish, and acrid taste. Sarcocolla, according to Pelletier, consists of 65.3 per cent. of a peculiar substance, considered by Thomson as holding an intermediate place between gum and sugar, and called *sarcocollin*, $C_{13}H_{23}O_6$, 4.6 of gum, 3.3 of a gelatinous matter having some analogy with bassorin, and 26.8 of lignin, etc. It is said to be purgative, but at the same time to produce serious inconvenience by its acrid properties. The Arabian physicians used it internally, and by the ancients it was employed as an external application to wounds and ulcers, under the idea that it possessed the property of agglutinating the flesh, whence its name.

Sarcosin. *Methylaminoacetic Acid. Methylglycocoll.* $CH_3NHCH_2CO_2H$.—This derivative of creatine occurs in deliquescent, transparent crystals of a sweetish taste, soluble in water and slowly soluble in alcohol. Melting point 210° to 215° C. (410°–419° F.). It is used in *uric acid diathesis* and *rheumatism*. *Dose*, eight to fifteen grains (0.5–1.0 Gm.).

Sarracenia. *Side-saddle Plant. Fly Trap. Pitcher Plant. Huntsman's Cup. Water Cup. Sarracenie*, Fr., G.—According to E. P. Porcher, the roots of *Sarracenia flava* L., and *S. variolaris* Michx., have long been used in the Southern United States in *dyspepsia*, and are tonic, laxative, and diuretic. Sheppard found them to contain lignin, coloring matter, resin, an acid salt of lime, and probably an alkaloid. Stan. Martin asserts that he has found in the root—(1) an alkaloid which he proposes to name *sarracenine;* (2) a resin; (3) a yellow coloring principle (probably identical with Schmidt's *sarracenic acid*); (4) extractive; (5) substances which constitute the framework of plants. Sarracenine is white, soluble in alcohol and ether, combines with acids to form salts, and with sulphuric acid forms handsome needles, which are bitter, and communicate this taste to its menstrua. (*Ann. Thér.*, 1866, 73.) E. Schmidt, however, found no alkaloid but discovered *sarracenic acid*. (*A. J. P.*, 1872, 213.) *Dose*, of tincture (two ounces in one pint), a fluidrachm (3.75 mils); of fluidextract, from ten to twenty minims (0.6–1.3 mils).

Sassy Bark. *Nkasa. Doom Bark. Casca Bark. Mancona Bark. Saucy Bark. Ecorce de Mançoine*, Fr. *Manconarinde*, G.—This bark is interesting chiefly from its employment by the natives of Western Africa as an ordeal in their trials for witchcraft or sorcery. (For details, see *P. J.*, lxv, 2.) This bark was first studied by C. A. Santos (*A. J. P.*, 1849, xxi, 97), and subsequently by Procter (*Ibid.*, xxiii, 301; xxiv, 195). It is obtained from *Erythrophleum guineense* Don, and is a large tree with spreading branches, doubly pinnated leaves, flowers in spike-like racemes, and leguminous fruit. The bark is in pieces more or less curved, with or without epidermis, in the former case somewhat fissured externally, of a dull red color diversified by whitish spots, brittle, presenting when cut transversely numerous fawn-colored spots surrounded by reddish-brown tissue, nearly inodorous, and of an astringent taste. A comprehensive description of *sassy bark* is given in the *Commentar zur oesterreichischen Pharmacopœia*, 1890, by Vogl; and in the *Résumé de la Matière Médicale et Toxicologique Coloniale*, by Corre and Lejuanne, the plant, fruit, seeds, etc., are carefully illustrated. Gallois and Hardy obtained the poisonous principle *erythrophleine* by making an alcoholic extract of the bark, exhausting this with water, evaporating, rendering this extract alkaline with ammonia, and treating with acetic ether. The alkaloid is a colorless, crystalline solid, soluble in water, acetic ether, alcohol, and amyl alcohol, insoluble in chloroform, benzin, and ether. In contact with sulphuric acid and black manganese oxide, a violet color (less intense than that produced with strychnine) is developed. Harnack and Zabrocki (*A. E. P. P.*, xv, 404) also prepared *erythrophleine*, and by the action of hydrochloric acid upon it obtained an acid they call *erythrophleic acid*, and a volatile alkaloid they call *mançonine*. The bark yields its virtues to water. Power and Salway examined sassy bark in 1912 and confirmed the presence of erythrophleine as described by Harnack. (*A. J. P.*, 1912, 337.)

According to the observations of Savage, made in Africa (*Charleston Med. Journ.*, 1859), sassy bark produces in the natives a feeling of constriction in the fauces, attended by prickling, and followed by numbness, with, after a toxic dose, stricture across the brow, severe pain in the head, coma, and death. The physiological action of erythrophleine has been studied by various observers, especially by E. Harnack and R. D. Zabrocki,

Gallois and Hardy, and Lauder Brunton, with results which are fairly concordant. Erythrophleine exercises a digitalis-like action on the circulation causing a slow, strong pulse, with a rise in the arterial pressure. These changes are certainly in great part due to the direct action upon the heart, but are also seemingly in part produced by a stimulating influence upon the muscle fibers or nerves in the walls of the arterioles. Purging was also noted as the result of an increased peristalsis, thought to be due to the local action of the poison. Vomiting is believed by Lauder Brunton to be the result of an influence upon the nerve centers, because it occurs when the alkaloid is given hypodermically. In fatal poisoning in the lower animals, convulsions are pronounced, and the respiration is also markedly affected. In 1888 L. Lewin asserted erythrophleine to be a powerful local anesthetic, whose action is more pronounced than that of cocaine. His paper gave rise to an extraordinary controversy, the outcome of which appears to be that, although the alkaloid is possessed of not very active anesthetic powers, it is for various reasons practically not useful. (See 17th edition, *U. S. D.*, p. 1739.) A solution of the strength of one-tenth of one per cent. is used as an application to the cornea.

Germain Sée asserts (*Méd. Mod.*, Dec., 1891) that, although sassy bark does not act well upon the heart, it gives great relief in *dyspnea*, the number of respirations being lessened and the inspirations being extraordinarily increased in depth. He gave of the alkaloid from one-fortieth to one-thirtieth of a grain (0.0016–0.002 Gm.); of the extract, from one-fourth to one-third of a grain (0.016–0.021 Gm.).

Satureja. *Satureja hortensis* L. *Summer Savory. S. Montana* L. *Winter Savory. Sarriette*, Fr. *Saturei. Bohnenkraut*, G.—An annual labiate plant resembling thyme in odor and flavor, growing spontaneously in the south of Europe, cultivated in our gardens as culinary herbs, and sparingly naturalized from New Brunswick to Michigan and southward.

Saururus. *Saururus cernuus* L. *Lizard's Tail.* (Fam. *Saururaceæ.*)—D. L. Phares, of Newtonia, Miss., considers this indigenous swamp plant of the Eastern and Central United States "laxative, antispasmodic, sedative, and slightly astringent"; useful in irritation of the kidneys, bladder, prostate, and urinary passages generally. The *dose* of the strong infusion was, with the plant either fresh or dried, from one to four fluidounces (30–120 mils) every fifteen or thirty minutes, or three or four times a day. (*A. J. P.*, 1867, 468.)

Saxifraga.—Garreau and Machelast have isolated from *S. crassifolia* L. and other species of this genus a crystallizable bitter substance, *bergenin.* It is obtained by boiling the stems of the plants with absolute alcohol, after the tannin has been removed by ether. It crystallizes in alcohol, has a bitter taste, melts at 140° C. (284° F.), and burns up completely at 300° C. (572° F.). It is soluble in 167 parts of 90 per cent. alcohol and in 830 parts of water, but is more soluble in these liquids at a boiling temperature; it is faintly acid to litmus, and is not changed by treatment with dilute sulphuric or hydrochloric acid, but by diluted nitric acid is converted into oxalic acid. Concentrated sulphuric acid decomposes it. Its formula is given as $C_6H_9O_3.H_2O$. Bergenin is asserted to be intermediate in its action between salicylic acid and quinine. (*A. Pharm.*, 1881, 293.) The rhizome of *Saxifraga ligulata* Wall., which is used in India in *dysentery*, has been found by David Hooper to contain about 16 per cent. of gallic and tannic acids, but no other active principles. (*P. J.*, Aug., 1888.)

Scarlet Red. *N. N. R.* 1917. *Amido-azotoluol-azo-β-naphthol. Biebreich scarlet. Rubrum Scarlatinum.* $CH_3C_6H_4.N : NC_6H_3(CH_3)N : N.C_{10}H_5.OH$.—In 1906 Fisher (*M. M. W.*, 1906, liii, 2041) discovered that the dye stuff known as scarlet red had the power of greatly stimulating the growth of epithelial cells. This observation was confirmed by Helmholz (*J. H. H. B.*, 1907, xviii, 365), and in 1908 Von Schmieden (*Cb. C.*, 1908, xxxv, 153) applied it practically for the purpose of stimulating epithelial growths in various surgical conditions, as *chronic ulcers, unhealthy granulations*, and the like. Since then it has been employed by a number of surgeons to stimulate the formation of skin not only in these conditions, but in *bed sores*, in unhealed *ulcers*, following extensive injuries or *burns*, and to promote skin formation after operations. It is usually applied in the form of an ointment containing from 4 to 8 per cent. of the curative agent. When the ulcer is very large it is recommended that the salve should be applied around the edges rather than over the whole surface of the denuded area. It has also been employed by Wolfrum and Cards (*M. M. W.*, 1909, p. 242) in the treatment of *corneal ulcers* after the loss of cornea whether due to injury or ulceration and by Rabaudi (*S. M.*, 1909, p. 344) in *sore nipples* and *erosions of the uterus.*

When the wound is suppurating profusely, scarlet red is of little value. It should be reserved for clean, dry ulcers which show little tendency to heal. It may be applied either in the form of the eight per cent. ointment or as a powder diluted with boric acid. It is not an entirely harmless remedy, for Lyle (*N. Y. M. R.*, Nov. 16, 1912) has reported a case of serious poisoning, characterized by nausea and vomiting, epigastric pain with fever following the application of scarlet red over extensive ulcerated surfaces. Irritation of the kidney has also been attributed to its use.

Amido-azotoluol.—The success which has followed the use of *scarlet red* in the treatment of wounds which refuse to become covered with epithelium led E. Hayward to test other dyes of allied chemical properties. He found that ortho-amido-azotoluol, a substance closely allied to scarlet red, was even more efficacious than scarlet red. Amido-azotoluol has the chemical formula $CH_3C_6H_4N.NC_6H_3(CH_3)(NH_2)$. Amido-azotoluol forms red crystals or a reddish-brown powder melting at 100° C. (212° F.). It is insoluble in water but readily soluble in alcohol, chloroform and ether. It is also soluble in fatty oils.

Several other compounds, closely allied chemically to scarlet red, have been employed for the same purpose. Among these are *pellidol* (*diacetyl-amido-azotoluol*), and *azodolen*, which is a mixture of equal parts of pellidol with an iodol compound called *iodolen.* Hayward (*M. M. W.*, 1909, p. 1836) asserts that *ortho-amido-azotoluol* is even superior in efficacy to scarlet red.

Schinus. *Schinus molle* L. (Fam. *Anacardiaceæ.*)—The *pepper tree* of South America yields a berry the size of a pea, having a flavor similar to a mixture of pepper and fennel. It has been introduced as a shade tree in Southern California. (*A. J. P.*, 1896, 215.) The leaves contain a volatile oil which is readily discharged, as after a rain when the air is filled with fragrance. Schimmel &

Co. examined the volatile oil distilled from the berries; it had the sp. gr. 0.850, the odor of phellandrene, and was soluble in alcohol. (*Ph. Rev.*, 1897, 114.) It has been used successfully in *gonorrhea* as a substitute for cubeb. The leaves, bark, and gum resin have been employed medicinally. (See *A. J. P.*, 1866, 1885, 1890; also *P. J.*, 1887.)

Schleich's Anesthetic Mixture.—In 1895 Schleich proposed the use of an anesthetic mixture based upon the theory that the ideal anesthetic should have a boiling point as near as possible to the temperature of the human body, so that elimination should take place from the lungs as rapidly as possible, with consequent immediate awakening from unconsciousness. He proposed the use of petroleum benzin as an inert diluent to lower the boiling point, but H. C. Wood, Jr., in a series of experiments (*P. M. J.*, April, 1899), proved that petroleum benzin acts both upon the heart and the vasomotor system as a paralyzant, and that its effect upon the respiratory center is even more powerful, while its anesthetic influence is exceedingly feeble. Clinical experience has confirmed his conclusions that the use of Schleich's mixture is attended by more danger than is that of either chloroform or ether, and the method has been abandoned.

The same surgeon has also introduced a method of local anesthesia which consists in injecting very dilute cocaine solutions between the layers of the skin. For details of this method, see Wood's *Therapeutics*, 14th ed., p. 52.

Scolopendrium. *Scolopendrium Scolopodendrium* (L.) Karst. *Asplenium Scolopendrium* L. *Phyllitis Scolopendrium* (L.) Newman. *Hart's Tongue.*—The fronds of this fern, which is indigenous both in Europe and America, have a sweetish, mucilaginous, and slightly astringent taste, and, when rubbed, a disagreeable oily odor. They were used as a deobstruent in visceral affections, as an astringent in *hemorrhages* and fluxes, and as a demulcent in pectoral complaints.

Scopola. *Scopolia. Belladonna Scopola. Scopola Belladonna. Japanese Belladonna* (incorrectly).—"The dried rhizome of *Scopola Carniolica* Jacquin (Fam. *Solanaceæ*), yielding, when assayed as directed below, not less than 0.5 per cent. of its alkaloids." *U. S. VIII.* The genus *Scopola* is the connecting link between *Atropa* and *Hyoscyamus*, resembling *Atropa* in leaf and flower and in the microscopical character of its rhizome, but differing in that its fruit is not a berry but is a pyxis resembling that of Hyoscyamus. For description of drug and its histological study, see Kraemer, *A. J. P.*, 1908, p. 459. The Japanese plant, *S. japonica*, is so closely allied to *S. carniolica* that its specific distinction is very doubtful; it has been separated upon the characters of the style being curved, the calyx-teeth unequal and the leaves less obovate and having much longer petioles than *S. Carniolica;* but Holmes has shown that the curved style occurs in *S. Carniolica. S. Carniolica* is a common plant in Bavaria, Austro-Hungary, and Southwestern Russia, usually in the hilly districts, where it grows in damp, stony places. Its general appearance is that of the belladonna, but it is much shorter, rarely growing above a foot in height, has thinner leaves, and is especially distinguished by its fruit being a transversely dehiscent capsule and by the presence of a distinct rhizome.

The rhizome was officially described as "of horizontal growth, more or less curved and shortly and sharply flexuous, cylindraceous and somewhat flattened vertically, occurring mostly in pieces from 2.5 to 7.5 Cm. long and 0.8 to 1.6 Cm. broad, often split before drying; upper surface marked with closely set, large, cup-shaped stem scars, margins irregularly contracted; externally varying from yellowish-brown to dark brownish-gray, finely and irregularly wrinkled longitudinally, obscurely annulate and more or less nodular-roughened; fracture short and sharp, exhibiting a yellowish-white bark, its corky layer dark brown, or pale brown, wood indistinctly radiate, and central pith rather horny; nearly inodorous; taste sweetish, afterwards bitterish and strongly acrid." *U. S. VIII.*

The Japanese rhizome is from 5 to 15 cm. long, about 1 cm. in diameter, rarely branched, cylindrical or slightly compressed, knotty, bent, with circular disk-like scars, of a pale brown color, not whitish when abraded, with a slightly mousy, narcotic odor, and a taste nearly free from bitterness. According to Thos. Greenish, the microscopical characteristics of the rhizome of *S. Carniolica* are very similar to those of belladonna root, the chief differences being that the bark is less thick, the dark line under the epidermis narrower, the vascular bundles neither so large nor so numerous, and the bundles of raphides less pronounced; the starch grains are also smaller and their shape less distinct. The structure of the rhizome of *S. japonica* was found to be the same as that of the European species. Kraemer (*loc. cit.*) has since shown that scopola possesses only reticulate tracheæ while in belladonna root the tracheæ possess both simple and bordered pores.

The alkaloid *scopolamine* (or *scopoleine*), $C_{17}H_{21}O_4N$, has been found to be the characteristic constituent of the root. (See p. 985.) Inactive scopolamine, $C_{17}H_{21}O_4N$, also known as *atroscine*, is present. It melts at 82° C. (179.6° F.), and yields by hydrolysis tropic acid and scopoline. Seward W. Williams states, as the result of the assay of many tons of the root of *Atropa belladonna* and of the rhizome of scopola, each of the best qualities occurring in the American market, that while the belladonna root yields on an average 0.50 per cent. of alkaloid, the scopola yields 0.58 per cent. See also *Proc. A. Ph. A.*, 1899, 285.

Fluidextract of Scopola, U. S. VIII, was made as follows: "Scopola, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, to make about *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix *eight hundred mils* [or 27 fluidounces, 24 minims] of Alcohol with *two hundred mils* [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with *three hundred and fifty mils* [or 11 fluidounces, 401 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Scopola is exhausted. Reserve the first *eight hundred mils* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly. Assay *ten mils* of this liquid as directed below; from the result thus obtained, ascertain by calculation the amount of mydriatic

alkaloids in the remainder of the liquid, and add to this enough menstruum to make each *one hundred mils* of the finished Fluidextract contain 0.5 Gm. of the mydriatic alkaloids from Scopola." *U. S. VIII.*

Assay.—"The method to be employed is identical with that given for Fluidextract of Belladonna Root (U. S. VIII), using *ten mils* of Fluidextract of Scopola." *U. S. VIII.*

Extract of Scopola, U. S. VIII, was made by evaporating the fluidextract and assaying it so that it contains 2 per cent. of mydriatic alkaloids. *Dose*, one-eighth to one-fourth of a grain (0.008–0.016 Gm.).

The physiological and medicinal properties of scopola are very similar to those of belladonna, but the crude drug has been scarcely used at all in internal medicine. It has been largely employed in America in the manufacture of belladonna plaster and much of the hyoscine of commerce in the last decade has been obtained from it. Its alkaloid *Scopolamine hydrobromide* is recognized in the United States Pharmacopœia. *Dose*, of the drug, one to two grains (0.65–0.13 Gm.); of the fluidextract, one-half to three minims (0.03–0.2 mil).

Scrophularia. *Scrophularia marilandica* L. (*S. nodosa* L.). *Figwort. Scrofula Plant. Scrofulaire*, Fr. *Kropfwurz. Kontenwurz*, G. (Fam. *Scrophulariaceæ.*)—This rather tall herb, having a square stem, opposite leaves and slender panicles of small, greenish-purple flowers, grows in rich open woods from New York to North Carolina and west to Kansas. Its leaves have when fresh a rank fetid odor, and a bitter, somewhat acrid taste; but these properties are diminished by drying. Water extracts their virtues, forming a reddish infusion, which is blackened by ferric sulphate. For histological study of root, see *P. J.*, 1896. Walz has obtained from it two proximate principles, which he names respectively *scrophularin* and *scrophularosmin*. (Mayer, *A. J. P.*, 1863, p. 295.) Figwort leaves were formerly considered tonic, diuretic, diaphoretic, discutient, anthelmintic, etc.; useful in *scrofula* and as a local application in *hemorrhoids*. Van de Moer (*P. J.*, 1896) affirms that the seeds are toxic, belonging to the digitalis group.

Scutellaria. *N. F. IV. Skullcap. Scullcap. Hoodwort. Madweed. Mad-dog* or *Sideflowering Scullcap. Blue Pimpernel. Hooded Willow-herb. Scutellaire*, Fr. *Helmkraut, Schildkraut*, G.—"The dried plant of *Scutellaria lateriflora* Linné (Fam. *Labiatæ*)." *N. F. Scutellaria* was official in the U. S. P. VIII, but was introduced into the N. F. IV.

Several species of scutellaria have attracted attention. *Scutellaria galericulata* L., which grows in wet places from Newfoundland to North Carolina and west to Nebraska, has a feeble, somewhat alliaceous odor, and a bitterish taste. It has been employed in intermittents, and externally in old *ulcers*. *S. integrifolia* L. is intensely bitter, and might probably be found useful as a tonic.

Scutellaria lateriflora is an indigenous, perennial herb, with a stem erect, much branched, quadrangular, smooth, and one or two feet high. The leaves are ovate, acute, dentate, subcordate upon the stem, opposite, and supported upon long petioles. The flowers are small, of a pale blue color, and disposed in long, lateral, 1-sided, leafy racemes. The plant grows in wet shaded places in the United States and Canada.

The dried tops are described as "about 50 cm. in length, smooth; stem quadrangular, branched; leaves opposite, petiolate, about 5 cm. in length, ovate-lanceolate or ovate-oblong, serrate; flowers about 6 mm. in length, in axillary one-sided racemes, with a pale blue corolla and bilabiate calyx, closed in fruit, the upper lip helmet-shaped. Odor slight; taste slightly bitter. Scutellaria yields not more than 12 per cent. of ash." *N. F.* H. Molisch and G. Goldschmidt (*Ph. Ztg.*, Dec. 4, 1901, 965) obtained from scutellaria and a number of other labiates an identical body, to which they gave the name *scutellarin*. It is present in all of the different scutellarias, being most abundant in the upper epidermis of the leaf, but found also in the roots, stems and flowers of the plant. It was further obtained from the leaves of *Galeopis Tetrahit* L., and of *Teucrium Chamaedrys* L. In *Scutellaria altissima* L., the presence of cinnamic and fumaric acids were also established. Scutellarin is obtained by boiling freshly gathered leaves for fifteen minutes in ten times their weight of water, filtering the decoction and adding from 1 to 2 per cent. of hydrochloric acid, which causes an abundant precipitate of scutellarin. If precipitation is effected from the hot solution, the scutellarin separates in the form of light yellow crystals. The formula $C_{10}H_8O_3$ has been assigned to scutellarin. Its alcoholic solution gives a red precipitate with lead acetate and an intense green color with ferric chloride, changing on heating to a red color if the reagent is not present in great excess; alcoholic potassium or sodium hydroxides, as also alkali acetates, produce reddish-yellow precipitates, which change to green on exposure to the air. Solution of barium hydroxide has the same effect. The green color is produced immediately if an oxidizing agent, such as chlorine or bromine water, is added.

Scullcap is as destitute of medicinal properties as a plant may well be, not even being aromatic. When taken internally, it produces no very obvious effects, and probably is of no remedial value, although at one time it was esteemed as a remedy in *hydrophobia*. It has also been used in *neuralgia* and *convulsive affections, chorea, delirium tremens*, and *nervous exhaustion* from fatigue or over-excitement. (*A. J. P.*, xxiii, 370; *N. J. M. R.*, v; *M. S. Rep.*, 1870.) *Dose*, thirty to ninety grains (2.0–5.8 Gm.)

Sedatin, *Para-valerylphenetidin*, is made by the action of phenetidin hydrochloride upon sodium valerate; it occurs in fine crystals It is soluble in hot alcohol, sparingly soluble in ether, chloroform, and petroleum benzine. It is said to act like antipyrine. (See *Valeridin*, p. 1656.)

Sedum. *Sedum acre* L. *Biting Stonecrop. Wall Pepper. Small Houseleek. Mossy Stonecrop. Joubarbe âcre, Poivre des Murailles*, Fr. *Mauerpfeffer, Steinkraut*, G. (Fam. *Crassulaceæ.*)—This European plant has escaped to some extent from the gardens and grows wild in New England. It is spreading moss-like, possesses small, very thick leaves and yellow flowers. It causes vomiting and purging, and applied to the skin produces inflammation and vesication. The fresh herb and the expressed juice have been used as an antiscorbutic, emetic, cathartic, and diuretic, and have been applied locally to old *ulcers, warts*, and other excrescences. Other species are less acrid, and are even eaten as salad in some parts of Europe. Such are *Sedum rupestre* L., and *S. album* L. *S. Telephium* L. was formerly employed externally to cicatrize wounds, and internally as an astringent in *dysentery* and *hemoptysis*, and is still esteemed by the common people in France as a vulnerary.

Ernst Mylius found in 100 parts of *Sedum acre* 2.2 parts of a soft, not acid resin, 12.80 parts of uncrystallizable sugar, and 12.40 parts of a soft acid resin, besides an alkaloid and inert substance. (*J. P. C.*, 4e sér., xvii, 81.)

Selenium. Se = 79.2.—This widely distributed element, discovered by Berzelius in 1817, belongs to the sulphur group, and its compounds occur in nature associated with sulphur compounds. It is most conveniently extracted from the lead chamber deposits of the sulphuric acid works. The presence of *selenium* in sulphuric acid has been objected to on account of its coloring substances yellow, even minute quantities present in sulphuric acid giving a yellow tint to cellulose. (*P. J.*, 1912, 47.) The physiological actions of the compounds of this metal have not been widely studied, but Chabrié and Sépicque (*C. R. A. S.*, cx) have shown that *selenous acid* is an irritant poison. According to Merck, a solution of selenous acid (0.5 per 100) is a valuable reagent for detecting alkaloids. (*M. R.*, 1900.) Wassermann (*D. M. W.*, 1911) from experiments upon mice reached the conclusion that selenium had a destructive action on *cancerous growths* which has led to some clinical trials of various compounds of the element, especially the combination of *eosin-selenium* and the colloidal forms known as *seleniol* and *electro-selenium*. The treatment must be regarded as still in an experimental stage.

Semecarpus. *Semecarpus venosa* (Fam. *Anacardiaceæ*), the *Tschongott Tree.*—The highly poisonous nature of the bark of this tree, which is a native of the Caroline Islands, is, according to Thoms and Mannich (*Ph. Ztg.*, 1902), due to the presence of *cardol* (*anacardic acid*).

Sempervivum. *Sempervivum tectorum* L. *Common Houseleek. Hen-and-Chickens. Grande Joubarbe*, Fr. *Hauswurz, Hauslauch, Dachwurz*, G. (Fam. *Crassulaceæ.*)—A succulent, perennial plant with imbricated leaves and cymes of rose-purple flowers. It is extensively cultivated. In Europe the bruised recent leaves of this plant are employed as a cooling application to burns and other external inflammations. The juice is said to cure *warts*.

Senecio. *N. F. IV. Life Root.—Senecio* was introduced into the N. F. IV. It is defined as follows: "The dried overground portions of *Senecio aureus* Linné (Fam. *Compositæ*), gathered when flowering." *N. F.* Various species of this composite genus have been domestically used in the treatment of *amenorrhea* both in Europe and America, and their value has been confirmed by various practitioners. (See *P. J.*, Dec., 1897.) The species specially used have been *Senecio vulgaris* L., *Common Groundsel, Seneçon*, Fr., *Kreutzkraut, Jacobskraut*, G.; an annual European plant introduced into this country and growing quite commonly in waste grounds, and the North American species, *S. aureus* L., commonly called *golden ragwort* or *liferoot* and growing in wet meadows in the Northern United States. It is described as follows: "Stems from 3 to 6 dm. in length, if entire bearing a basal rosette of leaves; sparingly clothed with successively smaller leaves and bearing at the summit several yellow heads in a loose corymb, white floccose when young, but mostly glabrous when expanded, radical leaves on long, slender petioles, mostly of rounded form from 5 to 7 cm. in breadth, the base often cordate, the summit rounded, the margin crenate-dentate; stem-leaves gradually changing from the shape of the radical leaves to lyrately-pinnate, then pinnatifid and sessile, and at length clasping, oblong, and incised; heads slender peduncled, from 12 to 25 mm. in breadth, the lance-linear involucral scales in about two series, closely appressed, rays about ten, bright-yellow, disk flowers very numerous, small, bearing a glabrous akene and a white pappus. Odor characteristically aromatic; taste bitter, slightly astringent and distinctly acrid and pungent. Senecio yields not more than 10 per cent. of ash." *N. F. IV.* The fluidextract is official in the N. F. IV and made from a menstruum of two volumes of alcohol and one volume of water. It is used in the *dose* of one fluidrachm (3.75 mils) three times a day.

In *S. vulgaris*, and in lesser amount also in *S. Jacobœa* L., Grandval and Lajoux (*Union Médicale du Nord-est*, xix, 1895) have found two alkaloids, *senecionine*, $C_{18}H_{26}NO_6$, which is slightly, and *senecine*, which is readily, soluble in ether. According to Wiet, senecionine is a paralyzant of the peripheral motor and sensory nerves, while Bunch has found that the alcoholic extract of *Senecio Jacobœa* is capable of producing a rise of the arterial pressure due to contraction of the arterioles, followed, if the dose has been large enough, by arterial dilatation with fall of pressure. (*B. M. J.*, 1900, ii, 212.) *Senecin* of the eclectic practitioners is made by precipitating the tincture with water and is not therefore a pure active principle.

The rhizomes of the Mexican species, *Senecio grayanus* Hemsl. and *S. cervariæfolius* Sch., constitute *maturin*, the plants being known as *matarique, maturin*, or *guerena*. They produce rise of temperature, dilatation of the pupil, and violent tetanic spasms. Henckel states that they contain a glucoside resembling digitalin. (*A. J. P.*, Jan., 1891; also *Nouv. Rem.*, 1888, and *P. J.*, March, 1889.) Several species of senecio, especially the *S. Jacobœa*, have been accused of causing poisoning in cattle which have eaten them. Cushny has found in the *S. Gladifolium* Watt two alkaloids, *senecifoline* and *senecifolidine*, which are actively poisonous, causing symptoms similar to those which have occurred in animals after eating the compound. The most characteristic pathological lesion was cirrhosis of the liver. The fluidextract of *S. vulgaris* has been recommended by Dalché and others in *dysmenorrhea* and *amenorrhea*. (*Bull. Med.*, 1904.)

Septoform is a condensation product of formaldehyde with members of the terpene, naphthalene, and phenol groups, prominent among which is *dioxynaphthylmethane*, $(C_{10}H_7O)_2.CH_2$. This preparation is offered in the form of a soap and also of an aqueous solution. It is said to be free from irritant properties and to be so strongly germicidal that a 1 per cent. solution will kill the cholera vibrio in five minutes, and the 3 per cent. solution the pus organism in three minutes. It has been chiefly used in veterinary practice, and for the disinfection of the hands (a 3 per cent. solution), or of instruments (5 to 10 per cent. solution). (*Th. M.*, xvi.)

Serums. *Normal Horse Serum. Normal Sheep Serum. Normal Goat Serum.* These liquids are obtained from the blood of the respective animals by inserting a large sterile needle into a vein and allowing the blood to flow through rubber tubing connected with the needle into covered vessels of one or more liters capacity. The blood is allowed to coagulate for about two days, either around a rod or other device previously inserted in the vessel, or spontaneously in the bottom of the container; the clot at the end of this period may be

squeezed free of serum by dropping a weight from the upper part of the vessel. The clot gathers in its meshes the red cells and the white cells of the blood, so that the fluid remaining to be siphoned off is a transparent liquid of a light yellowish brown color. This is called *blood serum.* If the clotting had been prevented by the addition of a citrate or oxalate and the blood cells separated by means of sedimentation, with or without centrifugation, the resulting fluid would be *blood plasma.* If, in the third place, the blood had been vigorously agitated by means of rough solid bodies such as pieces of broken glass in the container immediately upon being withdrawn from the animal, the fibrin or clot would have rapidly formed around these agitating bodies leaving the cells suspended in the fluid; such a fluid is called *defibrinated blood,* it resembles whale blood in appearance, but differs from it in having lost the property of spontaneous coagulation, it differs from serum in containing red blood cells and some white cells. The blood platelets and part of the white cells are destroyed by defibrination. All these operations must be carried out with an aseptic technic more strict than that of the surgical operating room, because blood and the fluids derived from it are excellent culture media for bacteria, and all bacterial contamination, whether pathogenic (disease causing) or not must be excluded. All the instruments and vessels must be sterilized—not by boiling—but in such a manner that even bacterial spores are destroyed. This requires dry heat at 170° C. (338° F.) for an hour and a half. Material such as rubber, which will not withstand this heat, may be sterilized by steam at 15 pounds pressure for half an hour, provided the boiler or autoclave is so arranged that all the air in the interstices of the material to be sterilized is withdrawn and replaced with saturated steam; the usual steam sterilization does not accomplish this.

Even with such precautions, serums are not usually considered safe unless preserved by the addition of some antiseptic, such as 0.5 per cent. phenol or cresol, or chloroform to saturation. As usually administered these quantities of preservative are without serious effect.

The serum of normal animals is used in therapeutics to promote clotting in *hemorrhage* or in hemorrhagic diseases. The other blood fluids described above are not available for this purpose—the plasma on account of its content of citrate or oxalate which prevents clotting, the defibrinated blood and whole blood on account of the red blood cells which they contain; the blood cells of another species might prove harmful to man. According to Howell's theory, clotting of the blood takes place when *thromboplastin,* contained in tissue cells or blood-platelets, is allowed to act on *antithrombin,* a substance normally present in the blood inhibiting clotting. *Prothrombin* is thus set free which then combines with the calcium of the blood in the formation of *thrombin* or *fibrin ferment.* This fibrin ferment in conjunction with the *fibrinogen* present in normal blood—forms the clot. It is thus seen that in blood serum most of the clotting factors have been partially or wholly used up in the production of the clot. Nevertheless, serum has seemed of value in many cases of hemorrhage, though there are other cases in which it is of no value. (See also under *Blood of Bullocks,* p. 1282.) Fresh serum is apparently more efficacious than old; it is therefore advisable to use serums whose date of production is stated. *Dose,* two and one-half to five fluidrachms (10–20 mils) hypodermically, or in urgent cases intravenously.

The occurrence of serum sickness and anaphylactic shock after injection of serum or its products has been mentioned under *Serum Antidiphthericum* (Part I, page 998). The same precautions should be taken in the use of normal serum. Horse serum appears to be less toxic—less likely to cause serum sickness than the serum of any other alien species, but in cases in which hypersensitiveness to horse serum is feared or proven, serum from the goat or sheep may be used. In hospitals freshly drawn rabbit serum, or whole human blood, is used for similar purposes.

No serum can be sold in interstate commerce except when produced in an establishment licensed by the Secretary of the Treasury. The requirements are those given under *Serum Antidiphthericum* U. S., except those for potency. There is no standard for the potency of normal serum.

Immune Serums.—This term includes the serum of animals in whose blood an immunity to any given bacterium or other harmful substance has been produced by the injection of that bacterium or harmful substance. This immunity may show itself in various ways. It is most notable, and most truly an immunity when, as in the case of antitoxic immunity, the serum actually protects another animal from the toxin or poison, or even cures the second animal if injected some time after the toxin. The word *toxin* can only be applied to those poisons which have the property of inciting such an immunity (*i.e.,* producing antitoxin) when injected into an animal in gradually increasing doses. The immunity may be antibacterial instead of antitoxic, that is, attacking the bacteria themselves rather than their soluble poisons or toxins. *Antibacterial immunity* in a serum may be manifest in its bactericidal or bacteriolytic properties; these two modes of action are generally taken as synonymous, but the term bactericidal refers especially to the killing of bacteria by the serum, as shown by tests of the numbers of bacteria present after its action, while bacteriolytic has reference to the gradual breaking up and dissolving of the bacteria as seen under the microscope. Antibacterial immunity is also sometimes demonstrable as a protective action, protecting for example guinea pigs which receive the immune serum against doses of the bacterium in question which kill other guinea pigs of the same weight not receiving the serum. Antibacterial immunity may be bacteriotropic or *opsonic,* which means that the serum in question in some way changes the special bacteria so that they are easily taken up and destroyed by the white blood cells. It is to be noted that immune serums are specific—that is, if antitoxic—they neutralize only the particular toxin which was used in their preparation, and no other; if antibacterial they have an antagonistic affinity for the exact species of bacterium with which the original animal was treated, and no other, or in some cases, only closely related bacteria. This fact of specificity is made of diagnostic use in the agglutinating property of immune serums (see Agglutination Test for Typhoid Fever, under *Diagnostic Tests,* p. 1360), and in their complement fixing power (see Complement Fixation Reaction for Syphilis, under *Diagnostic Tests,* p. 1359).

In the case of immune serums used for the treatment of disease this specificity is frequently so high as to be detrimental. Thus an antibacterial serum prepared from a given organism may be powerless against the same species of organism arising from other sources. In meningococcus,

streptococcus and pneumococcus infection this is particularly true. The organisms from different sources are called strains—and in spite of many different strains being used in the production of these serums, cases of meningitis, sepsis, or pneumonia occur in which the serums can be shown to have no influence against the infecting organism either in the body of the patient or in the laboratory. This is one of the causes of the poor success which has generally attended the use of serums other than diphtheria and tetanus antitoxin. Measures to overcome this difficulty have been taken, notably in anti-meningococcus and partially in anti-pneumococcus serum.

The material which is injected in the production of an immune serum is called the *antigen*, while the substance in the immune serum which gives rise to the different phenomena mentioned above—antitoxic, bacteriocidal, or bacteriolytic, protective, bacteriotropic or opsonic, agglutinative, complement fixing,—is called an *antibody*. Some workers hold that there is a different antibody for each function, while others take the view that a specific serum has only one antibody, with all these varied functions. It is certain, however, that in different serums these properties are present in different proportions, and consequently it is easier to conceive them as being exercised by different antibodies. Unfortunately, we have little means of knowing in a given case, which properties or which antibodies are the important ones in rendering a serum valuable to cure or prevent the infection in question, therefore we have no means of precisely measuring the worth of a serum.

Immune serums may be prepared against other substances than toxins and bacteria, as against foreign proteins, in which case a seventh property is apparent—that of precipitating the antigen used in its preparation. Blood cells of many other species also act as antigen for another series of immune serums; the antibody most apparent here is *hemolysin*, which dissolves the red corpuscles when added to the immune serum so that the corpuscles disappear and the fluid in which they were suspended takes on a clear red color (see Complement Fixation Reaction for Syphilis, under *Diagnostic Tests*, p. 1359).

All establishments manufacturing serums used in the prevention or treatment of human diseases are required to be licensed by the Secretary of the Treasury if the serums are sold in interstate commerce. The same requirements are prescribed as in the case of *Serum Antidiphthericum*, U. S. (Part I, p. 998), but unfortunately except in the case of diphtheria and tetanus antitoxins there are no potency standards for any serums, the reason is given above—the multiplicity of the antibodies and the uncertainty as to their relative importance.

Immune serums commonly contain preservatives and also are prone to cause serum sickness in the same way as antidiphtheric serum U. S. (q. v.). In this connection it is to be noted that the serums described in Part II are in general by no means as efficacious as the antitoxins, (Serum Antidiphthericum, U. S., and Serum Antitetanicum, U. S.), and further that they are usually to be administered in much larger quantities by the intravenous route if any benefit whatever is to be expected; the former consideration would cause one to hesitate if any possible danger were anticipated from their use, and the latter emphasizes the need of extreme caution unless hypersusceptibility to horse serum has been excluded.

Immune serums containing antibodies must be sharply distinguished from Vaccines (p. 1653) which contain antigen and force the human body to manufacture its own antibodies.

All serums lose in potency gradually and should be kept at a temperature between 4° C. and 15° C. (39.2–59° F.).

Antianthrax Serum (*Serum Antianthracum*). *N. N. R.* 1917.—This immune serum is prepared by injecting horses with gradually increasing doses of anthrax bacilli. The horses are then bled as described under Normal Horse Serum, p. 1602, and the serum collected. Considerable success has attended the use of this serum in the treatment of *anthrax* in animals, and some in man, if the serum happens to be a potent one and is administered early. *Dose*, 30 units to 100 mils intravenously or subcutaneously.

Antidysentery Serum (*Serum Antidysentericum*). *N. N. R.* 1917.—Certain bacilli, or groups of bacilli, have been found to be the cause of some forms of dysentery. These bacilli are classified generically as the dysentery bacillus, and are given various names, as *Shiga-Kruse* type, *Flexner* type, Strong type, Y type, according as their characteristics fall into one or another of these fairly well defined groups. Horses have been immunized by the injection of cultures of one or several of these types, and the serum used in the treatment of human *dysentery*. The results in many cases have been encouraging, giving a considerable reduction in mortality over similar cases treated without serum. Other reports have been negative; it appears that the type of bacillus used in immunizing the horse must be the same as that causing the particular infection, and further that infection with the Shiga-Kruse type is more benefited than infection with Flexner type. *Dose*, two and one-half to eleven fluidrachms (10–50 mils), subcutaneously or intravenously.

Antigonococcus Serum (*Serum Antigonococcicum*). *N. N. R.* 1917.—By injection of animals with gonococci, serum may be prepared which at times shows the properties of bacteriolysis, agglutination and complement fixation. Such serum has been used in the treatment of gonococcal infections, in part with favorable results. The serum seems to have no value in acute *gonorrheal urethritis*, and the lack of complete success in other cases may be due to the failure of antibodies to reach the seat of disease in sufficient concentration.

Antimeningococcus Serum. Antimeningitis Serum. Serum Antimeningococcicum. N. N. R. 1917.—The success attending the use of this serum in cases of *meningitis* caused by the *meningococcus* (*Diplococcus intracellularis meningitidis*) is one of the great triumphs of serum therapy, second only to the success of the antitoxins against diphtheria and tetanus. To immunize the horses used in producing the serum, cultures are injected, freshly killed, living, and partially disintegrated and dissolved. Unfortunately no definite standard has as yet been proven valid, by which the value of an antimeningococcus serum may be measured in the laboratory. More or less inert products are therefore frequently met with. Still another source of frequent failure of the serum lies in the fact, as described above, p. 1603, that there are many strains of the meningococcus, and the strain causing a given infection may be very different from any of those used in producing the serum; the specific antibodies fitting that particular strain would then be lacking and improvement could not be expected from the use of the serum.

The great step in advance in the use of antimeningococcus serum was in its application directly

to the seat of disease, instead of merely subcutaneously. The injection is made under the dural membrane of the spinal canal, that is, into the meningeal space. As in other successful serum treatment, early diagnosis and early application is necessary. The injection is best done without anæsthesia. The patient should be held firmly on his left side, with knees bent up nearly to the face, and with his back resting at the edge of the table or bed. The hands of the operator and the instruments must be sterilized. A stout needle with trocar at least 4 inches long should be used. The skin should be cleansed first, then treated with an antiseptic, such as tincture of iodin. The site for insertion of the needle is preferably the median line just below the fourth lumbar vertebra (on a line with the crests of the hip bone).

The needle is directed upward at an angle of about 35 degrees along the upper edge of the fifth lumbar spine until the point is felt to penetrate the dura, when the trocar is withdrawn and the spinal fluid allowed to flow out. This should be saved in a sterile container and examined microscopically. A turbid fluid, however, indicates meningitis and in case of doubt it is best to inject the serum. From forty-five to ten fluidrachms (3–50 mils) of serum (previously warmed) is slowly injected by gravity pressure, the amount being best determined by the fall in blood pressure according to Sophian's method. A drop of 20 millimeters is an indication to stop the injection at once. The injection should be repeated daily until the condition of the patient has definitely improved and the spinal fluid has been free from meningococci pus cells.

The amount of preservative in serum for intraspinal administration should not exceed 0.3 per cent. cresol or phenol. If the preservative is too concentrated, or if too much serum is injected, there is danger of collapse and even death. But the danger of the disease itself is much greater and no delay in instituting serum treatment should ensue by reason of fear on this ground.

Antiplague Serum. Yersin Serum.—The horse used for immunization receives killed cultures or living avirulent cultures of *Bacillus pestis* and finally living virulent ones. It is evident that such immunization must be carried out under special precautions in view of the danger involved in working with living plague bacilli. One virulent strain appears to be as effective as another. The resulting serum can be shown to have protective action on animals, but in the treatment of human *plague* only a moderate reduction in mortality is obtained—largely because the serum is not administered at the incipiency of the disease. *Dose,* 100 mils (three and one-third fluidounces) or more intravenously.

Antipneumococcus Serum. Serum Antipneumococcicum. N. N. R. 1917.—The pneumococcus (*Diplococcus pneumoniæ,* Weichselbaum) is present more often than any other organism as a causative factor in pneumonia. In one or more of its types it is found in about 60 per cent. of normal mouths or throats and may cause ordinary colds, severe grip-like infection, middle ear disease, ulcer of the eye, or meningitis. Serums have repeatedly been produced by immunizing animals against the pneumococcus, but the results have been variable. Römer, Neufeld, and Cole have conducted experimental investigations in serum therapy of *pneumonia;* it appears to be one requisite for success that the serum be produced by the use of the type of pneumococcus found in the patient to be treated. Certain of these types are more frequent than others and offer more promise. Other desiderata are that the serum be used early—on the first or second day of the disease if possible, and that large amounts—as much as 100 mils per dose—be injected intravenously. Local application in *corneal ulcer* and intraspinal administration in *meningitis* due to the pneumococcus have had some success.

Antistreptococcus Serum. N. N. R. 1917.—Many attempts have been made to produce therapeutically valuable antistreptococcus serum. In many commercial serums some antagonistic influence on streptococci can be demonstrated in the laboratory, but only rarely are authentic series of benefited cases reported. It seems to be necessary to introduce a large amount of the serum (100 mils or more) intravenously, and in such a serious disease as streptococcus infection the added strain on the eliminative mechanism caused by such quantities of foreign protein may turn the tide in the wrong direction. The Viennese reports of success with streptococcus serum therapy in severe cases of *scarlet fever* have not been confirmed in this country. The strong serum specificity of different strains of the bacterium may account for divergent results. The activity of antistreptococcus serum appears to be largely bacteriotropic.

Antivenomous Serums. Antivenins.—The snake poisons are true toxins and the serums prepared to combat them are true antitoxins. Theoretically, then, we should expect the excellent results of diphtheria and tetanus antitoxin to be duplicated in the serum treatment of *snake bites,* instead of the equivocal results of the antibacterial serums. Certain practical difficulties have interfered with such success. In the first place, the toxins of snake venoms are highly specific. Not only are there present in a given venom several different poisons, such as *hemorrhagins* (causing breaks in the blood vessels and consequent hemorrhages), *neurotoxin* (poisoning the vital center of the central nervous system), *coagulins* (causing clotting of the circulating blood), *hemolysins* (destroying the red blood cells), *hemoglutinins* (clumping the red blood cells)—but each of these is peculiar to its own species. Therefore to be effective, the serum must be derived from an animal immunized against the particular species of snake to be encountered. In the second place, very potent serums have not as yet been prepared—due largely to the difficulty in securing the antigen—snake venom—in large quantities. Thirdly, the serum must be on hand and used immediately.

In the case of the common North American poisonous snakes,—the rattlesnake, copperhead, and watermoccasin, hemorrhagins are the most important toxins. If antivenomous serums are available, they should be carried by the traveler and administered within a few minutes after the bite. Some time may be saved by the ligature cutting off the return flow of blood from the part affected. 100 mils or more of the antivenomous serum suited to the species of snake concerned should be injected intravenously, and more injected intramuscularly in the vicinity of the wound.

Sesamum. *Sesamum indicum* L. (Fam. *Pedaliaceæ.*)—The *benne* plant of our Southern States is annual, with a branching stem four or five feet high, and bearing opposite, petiolate leaves, varying considerably in their shape. The flowers are reddish-white, and stand solitarily upon short peduncles in the axils of the leaves. The fruit is

an oblong capsule, with small, oval, yellowish seeds.

There are some ten or twelve species referred to the genus *Sesamum*, the majority of which are natives of Africa. In India one or two species occur wild, one of these, *Sesamum indicum* L. (*S. orientale* L.), has been cultivated from time immemorial in various parts of Asia and Africa. From the latter continent it is supposed that seeds were brought by the negroes to the United States, where, as well as in the West Indies, it is now cultivated to a considerable extent. The plant above described will grow as far north as Philadelphia. The seeds are employed as food by the negroes, who parch them over the fire, boil them in broths, make them into puddings, and prepare them in various other modes. By expression they yield a fixed oil, which was introduced into the Pharmacopœia at the revision of 1880 and is official in U. S. IX. (See Part I.) Berjot obtained from the seeds 53 per cent. of oil by means of carbon disulphide. Rautenberg reported a series of severe poisonings from the intestinal injection of sesame oil. (*J. A. M. A.*, xlvii, p. 1962.) These accidents, he believes, are due to adulteration of the oil.

Benne Leaves.—These abound in a gummy matter, which they readily impart to water, forming a rich, bland mucilage, much used in the Southern States as a drink in various complaints to which demulcents are applicable, as in *cholera infantum, diarrhea, dysentery, catarrh, acute cystitis, strangury*, etc. The remedy has attracted attention also in the North, and has been employed with favorable results in Philadelphia. One or two fresh leaves of full size, stirred about in half a pint of cool water, will soon render it sufficiently viscid. With dried leaves hot water is used. The leaves also serve for the preparation of emollient cataplasms.

Sethia. *Sethia acuminata* Arn. (now *Erythroxylon lucidum* H. B. K.) (Fam. *Erythroxylaceæ.*)—The juice of this Ceylon plant or the powdered leaves —*dose*, fifteen grains (1.0 Gm.)—are affirmed to be an efficient vermifuge. (*P. J.*, April 7, 1883.)

Sida. *Mesbé. Sida rhombifolia* L.—*Queensland hemp* (Fam. *Malvaceæ*), *jelly leaf*, is largely used in Australia as a demulcent. It contains a large quantity of mucilage. The fluidextract has been asserted to possess expectorant properties and to be especially valuable in the treatment of *pulmonary tuberculosis*. Zink (*M. M. W.*, 1912), however, was unable to obtain evidence of any specific action in *tuberculosis*. *Sida paniculata* L. (*S. floribunda* H. B. K.), of Peru, which also contains a large quantity of mucilage, is said by Martinet to be a very active vermifuge, owing its powers, probably, to the extremely minute but very resisting spines which cover its leaves, the part used.

Siegesbeckia. *Siegesbeckia orientalis* L. (Fam. *Compositæ*).—This plant is used in the Mauritius Islands in *syphilis, leprosy*, and various skin diseases. A white, crystalline principle, *darutine*, has been discovered in it by M. L. Auffray. (*P. J.*, vol. xvi, 1047; also *B. M. J.*, June 25, 1887.)

Sienna. *Terra di Sienna.*—An argillaceous mineral, compact, of a fine texture, very light, smooth, and glossy, of a yellowish-brown or coffee color, leaving a dull orange trace when moistened and drawn over paper. By calcination it assumes a reddish-brown color, and is then called *burnt sienna*. In both the raw and burnt states it is used in painting. The best *sienna* is brought from Italy, but an inferior kind is found in England.

Silene. *Silene virginica* L. (Fam. *Caryophyllaceæ*). *Catchfly. Wild Pink.*—The wild pink, growing from Western New York to Minnesota and southward, was considered by the Indians poisonous and by Barton an anthelmintic. It is a slender herb having thin-spatulate or oblong-lanceolate leaves and deep crimson or scarlet flowers in a loose raceme.

Silex, Pulverized. *Silex Contritus* Lond. *Quartz.*—For mechanical purposes, in the making of aromatic waters, etc., the London Pharmacopœia formerly recognized under the name of *Silex Contritus* powdered *quartz;* but at present powdered purified talc, paper pulp and magnesium carbonate are employed. For details, see 17th edition, *U. S. D.*, p. 1741.

Pulverized silex is a harsh, white, tasteless powder, insoluble in water and most other solvents. Its sp. gr. is 2.66. In composition it is a *silicic oxide*, SiO_2. *Silicon* is an electro-negative element, which has been obtained in two allotropic states, called amorphous and crystalline silicon; the first corresponding to amorphous carbon and the second to crystallized carbon or the diamond, except that it is steel-gray in color. The second variety is hard enough to scratch glass but not topaz and has the sp. gr. 2.49. It is now made on a large scale as a product of the electric furnace, being used as a deoxidizing agent in the casting of some metals. Pure *silica* is easily prepared by acidulating commercial solution of sodium silicate with hydrochloric acid, heating and evaporating, and washing the precipitated silica.

Silk Peptone. *N. N. R.* 1917.—This is a preparation of peptone derived from silk and standardized to a nearly uniform optical rotatory power. It is white to a yellowish non-hygroscopic powder, easily soluble in water and used as a testing agent for peptolytic ferments in tissues or in stomach contents. It has no use in therapy.

Silphium. *Silphium laciniatum* L. *Polar Plant.* (Fam. *Compositæ.*)—The *rosin weed*, or *compass plant*, of Ohio, yields an oleoresin, which is said to be used in making chewing gum. (*A. J. P.*, 1881, 487.)

Silver Acetate. *Argenti Acetas.* $AgC_2H_3O_2$.—*Silver acetate* occurs in white crystals, soluble in about 100 parts of water at ordinary temperatures, freely soluble in hot water. It has been introduced by Zweifel (*Centralbl. f. Gynækologie*, 1900, No. 51) as a substitute for silver nitrate in the treatment of *ophthalmia* of new-born infants. He asserts that the one per cent. solution is in these cases much more effective than the older salt.

Silver Ammonio-chloride. *Argentii Ammonii-chloridum. Argentum Chlorato-ammoniatum.*—This substance is formed by saturating solution of ammonia, by the aid of heat, with silver chloride and allowing the liquid to cool in a stoppered bottle. It crystallizes in cubes. Silver ammonio-chloride has been used in the treatment of *chorea, epilepsy*, and *syphilis*, and as an anthelmintic, in *doses* of from one-twelfth to one and a half grains (0.005–0.1 Gm.). It is probably of little value.

Silver Atoxylate. *Argenti Atoxylas. Argatoxyl.* $NH_2C_6H_4As.O.AgO.OH$.—*Silver atoxylate* (*atoxylic silver*) is insoluble in water, and is the mono-silver salt of para-amino-phenylarsonic acid. According to Blumenthal, atoxylate of silver contains 23 per cent. of arsenic and 33 per cent. of silver. Silver atoxylate has been used chiefly to increase bodily resistance to infectious diseases. According to Rosenstein (*All. M. C.*, 1912) its beneficial effects are due in part to its bactericidal properties and in

part to a leukocytosis which it calls forth. It has been used in *puerperal septicemia, rheumatic fever, gonorrheal arthritis, scarlet fever, carbuncles,* and other infections. From five to six grains (0.3–0.4 Gm.) suspended in ten times as much olive oil may be injected intra-muscularly at intervals of from one to several days. The injections are often followed by abscess formation but it is stated that the abscesses formed are sterile.

Silver Caseinate. *Argonin. N. N. R.* 1917. *Argentum Casein.*—This is a white powder, of neutral reaction, prepared by mixing equivalent quantities of solutions of sodium caseinate and silver nitrate and precipitating with alcohol. It is readily soluble in warm or albuminous water, with difficulty in cold water. It is incompatible with acids and acid salts, but is not affected by chlorides. A 10 per cent. solution in warm water is said to be permanent in the dark. (A. Leibrecht, *Th. M.*, vii, 1895.) Fifteen grains (1 Gm.) of this substance contain as much silver as does one grain (0.065 Gm.) of silver nitrate. It makes a neutral solution in water, and has been very highly recommended by both German and American clinicians in the treatment of acute and chronic cases of *gonorrhea.* Its 10 per cent. solution causes no pain in acute gonorrhea. According, however, to the elaborate study of H. M. Christian, it is not of much service in the treatment of *posterior urethritis.* One hundred and sixty minims (10 mils) of a 2½ to 3 per cent. solution may in the acute stages of the disease be injected into the urethra and allowed to remain there for five minutes. A solution—0.3 ammonia water, 0.6 argonin, 100 of water—is said by R. Mayer to be much more powerful than argonin itself.

Silver Chloride. *Argenti Chloridum.* AgCl.—This is readily prepared by adding a solution of sodium chloride to one of silver nitrate, as long as it produces a precipitate. As first thrown down, it is a white, curdy substance, but it soon becomes discolored when exposed to the light. It is decomposed by solutions of the caustic alkalies, which convert it into oxide, but not by their carbonates. After the formation of the oxide in this way, the addition of sugar reduces it, and revives the silver. (Levol.) Silver chloride has been used in *syphilis, epilepsy, chronic dysentery* and *diarrhea,* and other diseases in which silver nitrate has been given, but is probably of no value. The *dose* is from one to two grains or more (0.065–0.13 Gm.), four or five times a day.

Silver Citrate. $Ag_3C_6H_5O_7$. *N. N. R.* 1917. *Itrol.*—This salt, which is almost insoluble in water, was introduced by Credé as a dusting powder for wounds. It is powerfully antiseptic and non-irritant. According to Marshall and Neave (*B. M. J.*, 1906, ii) it is a more powerful germicide than silver nitrate. It has been very highly recommended by Werler (*Derm. Zeit.*, vol. cxi) in the treatment of *urethritis,* as being a powerful gonococcocide and non-irritant to the mucous membrane. He employs a solution varying in strength from one part in four thousand to one in eight thousand, which is to be injected four times a day. Von Arlt (*Aerzt. Zentral-Zeit.*, 1905) employs it in various infectious conditions of the eye, such as gonorrheal *ophthalmia, trachoma* and the like. His method of using it is to dust the powder on the previously cleansed conjunctiva, and to rinse off after a few minutes, either with water or borax solution. Warler also commends it as a remedy in the treatment of chronic *cystitis.* Tilger and other surgeons have commended the remedy in the treatment of all forms of infected mucous membrane in saturated solution (1 in 3800). Pfonarlt (*W. M. W.*, 1908, No. 52) recommends the dusting of the conjunctiva with pure itrol in cases of *ophthalmia neonatorum, trachoma,* and other severe infections of the eyes, alleging that it is no more irritant than would be any insoluble foreign body. In using itrol, it should be remembered that it is easily decomposed, especially in the presence of organic matter, and should be kept well stoppered and protected from the light.

Silver Fluoride. *Tachiol. Arganti Fluoridum.* AgF = 126.88.—Mueller (*D. M. W.*, 1908) recommends this salt as an injection in *gonorrhea* in strengths of from 1 in 10,000 to 1 in 2000. Stronger solutions, he says, are locally irritant. The silver fluoride, as well as the silver silicofluoride (*isotachiol*), Ag_2SiF_6, have been suggested for the purpose of sterilizing drinking water. According to the experiments of Hetsch 5 Gm. per 1000 litres will destroy most of the bacteria, but when these were numerous 10 Gm. per 1000 litres are not sufficient, and the agent is therefore not suitable for this purpose.

Silver Gelatose. *N. N. R.* 1917. *Albargin.*—This substance, which is a compound of silver and gelatose, is a yellowish, shining, sometimes coarse powder which, in either cold or warm water, freely forms neutral dialyzable solutions. It contains 13 to 15 per cent. of silver. It is incompatible with tannin and chlorides which precipitate gelatose and silver, respectively. It affects albumin slowly and also precipitates cocaine solutions, but may be used with the alkaloid providing the double solution be freshly prepared at the time of administration. It is not quickly reduced by light, but should be preserved in amber-colored bottles. It was introduced by Bornemann (*Ther. Geg.*, March, 1901) for the treatment of *gonorrhea.* When there is much irritation, the 0.1 per cent. aqueous solution may be injected four or five times a day; in more chronic conditions the solution may be up to 2 per cent.

Silver Iodate. $AgIO_3$.—This is a white insoluble powder. It is used chiefly as antiseptic in various *catarrhs,* especially in *enteritis* and *gastritis.* The *dose* is from one-twelfth to one-sixth of a grain (0.005–0.01 Gm.).

Silver Iodide. *Argenti Iodidum. U. S.* 1890. AgI = 234.80.—This salt may be readily prepared by adding a solution of potassium iodide to one of silver nitrate, and washing and drying the precipitate, which should be kept in dark amber-colored vials, protected from light. This iodide is said to have three allotropic forms and a point of maximum density at about 116° C. (240.8° F.). (See paper by G. F. Rodwell, in *Chem. News,* xx, 288; xxi, 14.) The U. S. Pharmacopœia, 1890, described it as "a heavy, amorphous, light yellowish powder, unaltered by light, if pure, but generally becoming somewhat greenish-yellow, and having neither odor nor taste. Insoluble in water, alcohol, diluted acids, or in solution of ammonium carbonate, but soluble in about 2500 parts of stronger ammonia water. It is also dissolved by an aqueous solution of potassium cyanide, and by a concentrated solution of potassium iodide, and the resulting solutions yield a black precipitate with hydrogen sulphide test-solution or ammonium sulphide test-solution. When heated to about 400° C. (752° F.), the salt melts to a dark red liquid, which, on cooling, congeals to a soft, yellow, slightly transparent mass. When mixed

with ammonia water, it turns white, but regains its yellowish color upon being washed with water. If a small quantity of chlorine water to be agitated with an excess of the salt, the filtrate acquires a dark blue color on the addition of starch test-solution. *U. S.*, 1890.

Silver iodide in suspension has been recommended as an injection for gonorrheal *urethritis* by Siter and Uhle. For this purpose, it is generally prepared extemporaneously. The formula recommended by Wilbert (*A. J. P.*, 1906) is 2.2 Gm. of silver nitrate dissolved in 50 mils of mucilage of acacia and 45 mils of water and to this is added 2.2 Gm. of potassium iodide which is dissolved in 50 mils of water and thoroughly shaken. Such a suspension of silver iodide is marketed as *Silvodide*. J. C. and B. L. DeG. Peacock (*Proc. Penna. Pharm. Assn.*, 1916, p. 231) contribute a thorough review of the various methods for preparing this emulsion and conclude that mucilage of chondrus is the best suspending medium when thoroughly purified. For tests of purity, see *U. S. D.*, 19th ed., p. 1647. Silver iodide has been given in *doses* of one or two grains (0.065–0.13 Gm.) three times a day, in *epilepsy* and other chronic nervous diseases, but is devoid of value.

Silver Lactate. *N. N. R.* 1917. *Argenti Lactas. Actol.* $AgC_3H_5O_3 + H_2O$.—*Silver lactate* was introduced by Credé as a surgical germicide. It is affirmed that its injection renders an infected wound rapidly aseptic without much irritation. It is soluble in 15 parts of water, and may be used in very strong, even saturated, solution. D. A. Tilger finds that the application of the pure powder to the curetted infected sore causes only moderate burning pain of short duration and acts most happily. (*M. M. W.*, 1897.) Its therapeutic properties seem to be purely local, since E. Marx found that after injection of very large doses of it into animals it does not prevent the development of pathogenetic germs. It is almost certainly decomposed at the point of injection, but, unlike corrosive sublimate, it does not form an insoluble compound when brought in contact with tissues, and so is able to find its way through these tissues. Fifteen grains (1 Gm.) of it have been given hypodermically without more serious symptoms than some burning pain at the point of injection. According to Marx, a remarkable rise of temperature follows the use of it in very large doses. Actol has been used to a considerable extent in dentistry, decayed or decaying pulp being washed with a solution of the strength of 1 in 2000 and then dusted with itrol.

Silver Methylene Blue.—This silver salt occurs as a blue powder readily soluble in water and representing 20 per cent. of silver. According to Edelmann (*D. M. W.*, 1913, p. 2292) it is germicidal in strengths of 1 part in 160,000 and contrary to many other anti-bacterials, exercises a considerable disinfectant power in the blood, 1 part in 80,000 exhibiting a distinctly antiseptic action. Doses of 0.1 Gm. per kilo injected subcutaneously produce no toxic effects in rabbits. It has been used not only as a local application, but as an internal disinfectant in *septicemia, rheumatic fever* and other infectious diseases. The *dose* recommended is from two to six grains (0.13–0.4 Gm.), either subcutaneously or intramuscularly.

Silver Methylene-nucleinate. *N. N. R.* 1917. *Sophol. Silver formo-nucleinate.*—This is a dark yellow, tasteless, odorless powder, readily soluble in water. When heated it gives off formaldehyde, a residue of metallic silver being left behind. Its solutions are not stable. It contains 20 per cent. of silver.

Sophol is asserted to possess a powerful germicidal action without any irritant effect upon mucous membranes. According to Vollert (*Ther. Neu.*, July, 1906), a 0.37 per cent. solution of sophol is bacteriologically equivalent to a 1 per cent. of protargol. It has been used chiefly in ophthalmic conditions, especially *gonorrheal ophthalmia* and also in non-specific cases of *conjuctivitis* in strengths of from 5 to 10 per cent. While apparently of much value for the purpose of destroying bacteria located on the superficies of the conjunctiva, Dreser (*A. J. P.*, xviii) states that it is lacking in penetrating power and is less valuable than silver nitrate after the germs have passed through the epithelium.

The solutions should be freshly prepared, as on standing, formaldehyde is liberated which is likely to prove irritant.

Silver Nitrate Ammonia Albumose. *N. N. R.* 1917. *Hegonon.*—It is asserted to contain approximately 7 per cent. of silver organically combined. It is not precipitated by albumin or sodium chloride.

Hegonon has been employed as an antiseptic in *gonorrhea* by Klingmuller. (*M. M. W.*, 1910.) It may be used in strengths of 1 in 400 to 1 in 3000.

Under the title *Argentamin* the N. N. R., 1917, recognizes an 8 per cent. solution of silver nitrate in a 15 per cent. aqueous solution of ethylene diamine. It is a clear, strongly alkaline liquid, sp. gr. 0.97, which does not precipitate albumin or chlorides. On exposure to air it is liable to turn yellow, but can be cleared by filtration. Its use in medicine was proposed in 1894 by Jean Schaeffer. (*Zeitsch., f. Hyg. u. Infektions*, 1894, xvi, Bd. ii.) Hoor used it in a large number of eye cases; he asserts that it causes less pain and irritation than the silver nitrate, and penetrates deeper. He used a 5 per cent. solution in the eye from one to four times a day in the same cases as those in which silver nitrate is useful. According to Aschner (*Orv. hetil.*, 1895), it is well borne by the posterior urethra in as strong solution as 1 to 250; but the anterior urethra will not bear more than 1 to 2000. An aqueous solution containing 10 per cent. of argentamin with 30 per cent. of a 1 per cent. solution potassium bichromate has been used instead of silver nitrate as a stain for histological examination of the nerve tissues. (*Ph. Ztg.*, 1910, No. 43, 436.)

Silver Orthophosphate. *Silver Phosphate. Argenti Phosphas.* $Ag_3(PO_4)$.—This substance is prepared by dissolving silver in concentrated orthophosphoric acid; the vitreous mass which results, while still melted, is dissolved in water acidulated with phosphoric acid, yielding a permanent solution. Spretzka (*Rév. Med. Pharm.*, v, 292) asserts that it is a valuable remedy in *gonorrhea*. The injection should contain 0.025 to 0.05 per cent. of the salt, increasing gradually to 0.25 or even 0.5 per cent.

Silver Phenolsulphonate. *Argenti Phenolsulphonas. Silver Sulphocarbolate. Silberol.* $C_6H_4(OH)SO_3Ag$.—A crystalline powder containing 28 per cent. of metallic silver, soluble in water; proved to undergo spontaneous decomposition, but said to be more permanent than itrol. Originally introduced by Zanardi as having the antiseptic properties without the corrosive action of silver nitrate, silberol has been employed by various practitioners in the treatment of *gonor-*

rhea and *ophthalmic inflammations*, and as a germicide in ocular surgery. It is asserted that a 2 per cent. solution is well borne as an antiseptic after operations upon the eye; also that when it is used as a substitute for silver nitrate silberol must be employed in twice as concentrated solution.

Silver Picrate. *Silver tri-nitro-phenylate. Picratol.* $C_6H_2O(NO_2)_3Ag. + H_2O$.—This occurs as yellowish crystals and said to represent 30 per cent. of silver. It is soluble in 50 parts of water. It is used as an antiseptic in *gonorrhea* and other *catarrhs* in strengths of from one-half to two per cent.

Silver-potassium Cyanide. *Silver and Potassium Cyanide.*—This occurs as colorless crystals readily soluble in water and very sensitive to light. According to Philippson it is about equally as poisonous as potassium cyanide and very powerfully bactericidal. He has employed it for washing out the bladder and urethra. He employs solution ranging from 1 in 7000 to 1 in 1000.

Silver Protalbin. *Largin.*—This is a compound of silver and protalbin, which occurs as a whitish powder, soluble in water to the extent of 10.5 per cent., freely soluble in glycerin, blood serum, and peptone solution. Not precipitated by chlorides nor yet by albumin, and containing 11.1 per cent. of silver. In brown bottles it keeps unchanged indefinitely. Owing to the fact that it does not coagulate albumin its penetrating powers when brought in contact with the mucous membrane are very great, and it is claimed by many German clinicians that as a specific germicide in the treatment of *gonorrheal affections* it is pre-eminent. In male *gonorrhea* the strength of the injection should be one-fourth of one per cent., gradually increased up to two per cent. In women the parts may be irrigated with from a one-half to one per cent. solution, after which a 5 per cent. largin bougie may be held in position by a cotton plug for fifteen minutes and the part again irrigated with a 0.5 per cent. solution of largin. Largin is also largely used in the treatment of infectious *conjunctivitis* and catarrhal *corneal ulcers* in the form of gelatin tablets containing one per cent.

Silver Proteinate. *N. N. R.* 1917. *Novargan.*—This is a fine yellow powder, soluble, at ordinary temperatures, in twice its weight of water. It is stated to contain 10 per cent. of silver, and to be actively germicidal. It is markedly astringent, and practically non-irritant, even in relatively concentrated solution. It has been used in the treatment of various *gonorrheal diseases*, in strengths of from two to ten per cent.

Silver Quinaseptolate. *Argenti Quinaseptolas. Argentol.* $C_9H_5N.OHSO_3Ag$.—This substance is a yellow powder, sparingly soluble in water, which was introduced into medicine by Credé on account of its readily splitting up into oxyquinoline and metallic silver. Both septic matters and intestinal juices are said to produce this change. It has been employed either as a dusting powder or in the form of spray, or injection, 1 in 300 to 1000, in *chancres*, *gonorrheas*, and various other surgical infections. C. Cipriani asserts that it is a valuable intestinal antiseptic of which 15 grains (1 Gm.) may be given safely in the twenty-four hours if necessary. It is said also to be an active non-irritant antiseptic with marked hemostatic properties.

Silver, Soluble. *Argentum Solubile. Argentum Colloidale. Soluble Silver.—Colloidal Silver. N. N. R.* 1917.—Several allotropic modifications of silver were discovered by Carey Lea in 1891. One of these has been introduced into medicine. "Soluble Silver," so called, can be prepared by taking a mixture of 30 Gm. ferrous sulphate dissolved in 100 mils of water and 36 Gm. of crystallized sodium citrate dissolved in 140 mils of water and pouring this mixture with stirring into 100 mils of a 10 per cent. silver nitrate solution. After allowing the precipitate to settle, the supernatant liquid is poured off, the precipitate dissolved in water, and again precipitated with absolute alcohol. When dried, the colloidal silver is a bluish or green-colored mass, which dissolves in water with a deep red color, but is precipitated from its solution by the addition of salt solutions. It contains 97.2 per cent. silver. Chassevant and Posternak find the collargol of commerce does not contain more than eighty-seven per cent. of silver, the rest being albuminous matter. (*C. R. S. B.*, 1903, lv.)

There are at present two forms of so-called colloidal or soluble silver employed in medicine, one of which is prepared by chemical means, and the other by electrolytic methods. The manufacturers of the latter preparations claim that the therapeutic virtues of the electrically prepared colloidal silver are much more clearly established than those of the chemically prepared varieties.

Colloidal silver was introduced into medicine by Credé wih the idea that it would possess the germicidal properties of silver, and being nontoxic, might be used internally for the control of various bacterial infections. It has been used very extensively in the treatment of *septicemia, rheumatic fever, gonorrheal arthritis, diphtheria, cerebro-spinal meningitis*, and other infectious diseases. While a large number of clinicians have been enthusiastic in their praises of its efficacy, there is as yet no well-supported theory of its mode of action, and a number of careful observers have denied that it possesses any therapeutic virtues whatsoever. Whatever may be the real value of this remedy, it is evident that it does not act as Credé had expected, as an antiseptic in the blood. In the first place, Brunner has shown that its germicidal action is extremely feeble, and Cohn (*K. T. W.*, 1905) found that within forty-five minutes after its injection the silver had disappeared from the blood entirely. This same observer has stated further that it had neither prophylactic nor curative properties in rabbits, against infection with the staphylococci. On the other hand, Dunger (*M. M. W.*, 1907) found that its injection lead to pronounced leukocytosis, and his conclusions have received considerable confirmation. It is claimed also that colloidal silver acts, like other colloidal metals, as a catalytic agent, and thereby aids in the destruction of the toxins.

The beneficial effects, however, which have been attributed to the local application of colloidal silver in *rhinitis, cystitis* and *conjunctivitis*, would seem to indicate that under some circumstances it may exercise antibacterial properties. The evidence for and against the practical value of colloidal silver is so contradictory that it is impossible to determine its utility.

The most widely used preparations of colloidal silver are as follows:

Collargol. N. N. R. 1917.—This occurs in bluish-black scale-like pieces which, with 20 parts of distilled water, yield a brownish colloidal solution

which is permanent if protected from light and heat. It is asserted to represent over 80 per cent. of metallic silver. It may be injected intravenously in solutions of from 2 to 5 per cent. strength, administering an amount of the solution equivalent to one to five grains (0.065–0.32 Gm.) once or twice a day. It is also widely employed in the form of a 15 per cent. ointment, *Unguentum Credé*, of which one-half to one drachm (1.8–3.75 Gm.) is applied at a *dose*, being vigorously rubbed into the skin.

Electrargol, N. N. R. 1917, is marketed in bottles and in sealed tubes. The *dose* is eighty to one hundred and sixty minims (5–10 mils) injected intramuscularly or directly into a vein.

Cargentos, N. N. R., 1917.—This is a *colloidal silver oxide*, which is said to represent 50 per cent. of metallic silver.

Lysargine.—This form of colloidal silver occurs as steel-gray shining scales which are readily soluble in water.

Argoferment is a colloidal silver preparation manufactured by an electrolytic process.

Silver Thiohydrocarburo-sulphonate. *Argenti Thiohydrocarburo-sulphonas. Silver Sulphoichthyolate. Silver Ichthyol. Ichthargan. N. N. R.* 1917.—This compound of ichthyol-sulphonic acid and silver is a brown amorphous stable powder, freely soluble in water, glycerin and diluted alcohol, insoluble in alcohol, ether, and chloroform. Its aqueous solution blackens with exposure to light, and in concentrated solution it is precipitated by sodium chloride and by albumin, the albuminous precipitate being redissolved by an excess of albumin. It is said to contain about 30 per cent. of silver and 15 per cent. of sulphur.

Wood (*N. Y. M. J.*, 1903, lxxvii) found that, although ichthargan is much less poisonous, its physiological action is the same as that of silver nitrate. The germicidal power of ichthargan is certainly equal, and probably superior, to that of silver nitrate, and it is far less irritant. It is therefore, a very valuable remedy for local application in the treatment of various infectious conditions, especially those involving mucous membranes. In *tonsillitis* and *pharyngitis* it may be applied to the throat with a swab in strengths of from 5 to 10 per cent. In *urethritis* for injections, solutions of 1 in 500 to 1 in 3000 may be used; for irrigations from 1 in 2000, to 1 in 5000.

Unna (*Med. Klin.*, 1913) highly recommends the use of ichthargan in various *skin diseases*, especially *psoriasis* and *chronic eczema*. He uses an ointment varying in strength from 5 to 15 per cent.

In *eczema, ulcerations, phlegmons*, and in *lymphangitis*, the ointment varying from 1 to 15 per cent. is advised, well rubbed into the adjacent healthy skin, previously thoroughly cleansed, and also applied directly to the affected surface, if it be exposed. Ichthargan has also been administered internally with asserted excellent results for the relief of *gastritis* and especially of *gastric ulcer*. *Dose*, one-twentieth to one-eighth of a grain (0.003–0.008 Gm.) in half a fluidounce (15 mils) of water, on an empty stomach.

Silver Vitellin. *Argentic Vitellin. Argyrol. N. N. R.* 1917.—This substance is said to be produced by extracting gliadin from wheat, treating it in an autoclave with dilute hydrochloric acid under pressure, and obtaining thereby a white granular precipitate which is said to be of the nature of a vitellin, and then combining this with silver, the resulting product being a dark brown powder containing 30 per cent. of metal. *Silver vitellin* is so soluble that one ounce may be dissolved in three drachms of water.

Argyrol has been used chiefly in the treatment of *conjunctivitis* and *urethritis*, especially of the gonorrheal type. Its value in these conditions, however, certainly does not depend upon any direct bactericidal effect, for this is extremely feeble. Post and Nicoll (*J. A. M. A.*, 1910, lv) have found a 50 per cent. solution is not certainly fatal to bacteria, even after thirty minutes' exposure, which finding is in harmony with the conclusions of other investigators. On the other hand, many clinicians believe it to be a very valuable remedy in this class of cases, and it is possible that it has some therapeutic virtue at present not explained, perhaps, as some believe, owing to a solvent action upon the pus, or perhaps due to some decomposition caused by the secretions.

It is one of the least irritant of all the silver preparations, and may be used in the urethra in strengths of from 1 to 10 per cent., while in *gonorrheal ophthalmia* it has been employed in concentrations up to 30 per cent.

Simaruba.—Under this name the U. S. P. formerly recognized the bark of the root of *S. amara* Aublet (*S. officinalis* DC.) *Ecorce de simarouba*, Fr. *Simarubarinde, Ruhrrinde*, G. *Corteccia di Simaruba*, It. *Corteza de Simaruba*, Sp. (Fam. *Simarubaceæ.*) This is a tree of considerable height, having alternate branches, with a bark which in the old tree is black and somewhat furrowed, in the young is smooth, gray, and marked here and there with broad yellow spots.

Simaruba bark is in long pieces, from 4 to 12 cm. wide and 2 to 5 mm. thick, folded lengthwise, light, flexible, tenacious, very fibrous, externally of a light brownish-yellow color, rough, warty, and marked with transverse ridges, internally of a pale yellow. It is without odor, and of a bitter taste. It readily imparts its virtues, at ordinary temperatures, to water and alcohol. The infusion is at least equally bitter with the decoction, which becomes turbid as it cools. Its constituents, according to Morin, are a bitter principle identical with *quassin*, $C_{10}H_{12}O_3$, to which Gilling (*P. J.*, 1908, lxxxi) ascribes the formula, $C_{22}H_{30}PO_9$, a resinous matter, a volatile oil having the odor of benzoin, malic acid, gallic acid in very minute proportion, an ammoniacal salt, calcium malate and oxalate, some mineral salts, ferric oxide, silica, ulmin, and lignin.

It is a native of French Guiana and the Islands of Dominica, Martinique, St. Lucia, St. Vincent and Barbadoes, in the West Indies. A closely related species, having, however, dicœcious instead of monœcious flowers, flourishes in Jamaica, San Domingo, Bahama Islands, Panama and Guatemala, extending even to Florida; it is called in Jamaica *mountain damson*, and is known as *S. glauca* DC. (*S. officinalis* Macf., not DC.) The two species have probably identical medicinal properties. The bark of the root is the part employed, the wood being nearly tasteless and inert. The middle bark contains much resin. A decoction of the bark and leaves of *S. versicolor* St.-Hil. (*Cortex Paraibæ*), is employed in Brazil as an antidote for snakebites and in the treatment of *syphilis* and *tapeworm;* the powder is used against vermin.

Simaruba possesses the same tonic properties as other simple bitters. In large doses it is said to purge and vomit. On account of its difficult pulverization, it is seldom given in substance.

The best mode of administration is by infusion. The *dose* is from twenty grains to a drachm (1.3–3.9 Gm.).

Simulo.—The dried fruit of *Capparis coriacea* Burch., one of the *Capparidaceæ*, has been recommended as a palliative in *epilepsy;* also in *chorea.* (See *T. G.*, 1888, 1889; and *Th. M.*, Aug., 1888.)

Sirolin.—This is a syrup containing approximately 7 per cent. thiocol (see p. 1640). It has been used in the same class of pulmonic diseases as creosote. The adult *dose* is one fluidrachm (3.75 mils).

Sisymbrium. *Sisymbrium officinale* (L.) Scop. *Hedge Mustard. Herbe aux chantres, Tortelle,* Fr. *Wildersenf, Hederich,* G. (Fam. *Cruciferæ.*)—This annual, growing in Europe and in waste grounds in the United States, is said to be diuretic and expectorant, and has been recommended in chronic *coughs, hoarseness,* and ulceration of the mouth and fauces. The juice of the plant may be used mixed with honey or sugar, or the seeds may be taken in substance. *Sisymbrium Sophia* L., or the *flax weed,* a plant which grows sparingly in waste places in the United States, was formerly official. It is of a pungent odor when rubbed, and of an acrid, biting taste. W. Zopf attributes its poisonous qualities to a volatile alkaloid. (*Zeit. f. Nat. Pharm. Central.*, 1894, 494.) The herb has been used externally in *indolent ulcers* and the seeds internally in *worms,* calculous complaints, etc. *Diplotaxis muralis* DC., (*S. Murale* L.), a plant growing about Atlantic ports, has been used in France in *scurvy, scrofula,* and other cachetic affections, especially associated, in the form of a syrup, with potassium iodide. (*Ann Thér.*, 1863, 126.) Grazing sheep are said to be killed in Southern France by feeding on *Diplotaxis tenuifolia* DC., and human poisoning has occurred. This species is also sparingly localized like D. *muralis.* George Heyl has separated a toxic and apparently uncrystallizable alkaloid. (*Ap. Ztg.*, May 30, 1900.)

Sium.—*Sium cicutæfolium* Schrank (fam. *Umbelliferæ*), which grows in British America and the United States, particularly along the water courses of the valleys of the Pacific slope, and is the *hemlock water parsnip* of this country, is positively asserted to be poisonous. A. R. Porter and N. Rogers (*A. J. P.*, 1876, 348, 483) found in it an active resinous body, toxic to animals. *Oil of Sium cicutæfolium* is stated by Rabak to be found in the plant in the proportion of 0.5 per cent. It is yellow and has an odor resembling that of caraway. (*Mid. Druggist,* 1905, 5.) *S. Sisarum* L., or *skirret,* a plant of Chinese origin, cultivated in Europe, has a sweetish, somewhat aromatic root. The latter is used in much the same manner as the oyster plant and parsnip. It is supposed to be a useful diet in chest complaints.

Skimmia. *Skimmia japonica* Thumb. *Miramashikimi.* (Fam. *Rutaceæ.*)—From this dwarf-growing holly-like shrub, which is cultivated on account of its dark, shining, evergreen leaves and clusters of bright-red berries, Eykman separated a glucoside, *skimmin,* and a decomposition product, *skimmetin.* (*Abhandl. d. Tokyo Diagaku.*, No. 10, Tokyo, 1883.) J. Honda (*A. E. P. P.*, Oct., 1904), however, finds that the activity of the plant depends upon the presence of the crystalline alkaloid, *skimmianine.* It is a muscle poison, producing no primary excitement in the muscle, but an increasing paralysis, the influence of the alkaloid extending to involuntary muscles, such as the heart, so that in mammals arterial pressure is progressively decreased.

Skin Varnishes.—Unna has devised a series of preparations for forming thin coverings on the skin. We reproduce the most important formulas.

Bassorin Varnish.—The pure bassorin basis is obtained, according to Elliot, by passing tragacanth mucilage (15 to 100) through a filter heated by steam, evaporating, and mixing with glycerin. A similar basis may be prepared by stirring 5 parts powdered salep with 95 parts cold water until a smooth mucilage is obtained, then heating for half an hour on the steam bath. The salep basis contains less bassorin, but more starch.

Casein Varnish.—The casein obtained by coagulating skimmed milk with rennet at a temperature of from 35° to 40° C. (95°–104° F.) is washed and dried until it forms a yellowish-white, sandy powder soluble in alkaline solution. In preparing this varnish the casein is dissolved by means of borax. For 20 parts casein 2.5 parts borax and 77.5 parts water furnish a rapidly drying uniform covering material. The alkaline characters of the borax are masked by the casein. Admixtures of heavy pulverulent substances readily settle out of this basis, and it is requisite to distribute them by shaking. A varnish of casein and glycerin is prepared by dissolving the casein in 3 or 3.5 parts of ammonia water, adding a quantity of glycerin equal in weight to the casein, and heating to drive off the ammonia. The resulting mass mixed with twice its weight of boiling water gives an excellent permanent emulsion.

Amber Varnish.—Made by dissolving a mixture of amber and turpentine in alcohol. It must not be used as a vehicle for the application of zinc oxide.

Castor Oil and *Shellac Varnish.*—With 1 part shellac, 1½ parts castor oil, and 3 parts alcohol, a varnish is obtained which forms a good flexible covering easily removed by alcohol.

Canada Balsam and *Collodion Varnish.*—Sixteen parts collodion with 1 part Canada balsam furnish a material suitable for the application of pyrogallol, and it can be easily removed by alcohol.

Castor Oil and *Collodion Varnish.*—Eight parts collodion and 1 part castor oil.

Lead Ricinoleate Varnish.—One part lead oxide heated with 1½ parts castor oil to saponification, and mixed with 2 parts absolute alcohol, gives a good skin varnish.

Chrysarobin Amber Varnish.—One part chrysarobin and 20 parts amber dissolved in turpentine.

Pyrogallol Shellac Varnish.—One part pyrogallol, 1 part castor oil, 5 parts shellac, and 15 parts absolute alcohol.

Salicylic Acid, Canada Balsam, and *Collodion Varnish.*—One part Canada balsam, 10 parts collodion, and 3 parts salicylic acid.

Zinc Oxide, Castor Oil, and *Collodion Varnish.*—Two parts zinc oxide, 2 parts castor oil, and 16 parts collodion.

Zinc and *Lead Ricinoleate Varnish.*—Five parts lead ricinoleate, 8 parts zinc oxide, 8 parts absolute alcohol, and, lastly, 1 part each of collodion and ether.

Ichthyol Borax Casein Varnish.—Five parts sodium ichthyolate and 15 parts borax casein varnish.

Sulphur Glycerin Casein Varnish.—Five parts sulphur and 15 parts glycerin and casein varnish.

Zinc Oxide Salepbassorin Varnish.—Two parts zinc oxide and 18 parts salepbassorin varnish.

Zinc Ichthyol Tragacanth Bassorin Varnish.—One part sodium ichthyolate, 2 parts zinc oxide, and 17 parts tragacanth bassorin varnish.

Smalt. *Smalts. Azure.*—When the impure cobaltic oxide, obtained by roasting the native arsenide of that metal, is heated with sand and potassium hydroxide, the mixture melts, and a beautiful blue glass results, which, when reduced to powder, forms smalt or azure. It is used chiefly in painting, and for coloring glass and porcelain.

Sodium Argaricinate. $C_{14}H_{27}OH(COONa)_2$.—This salt occurs as a white, tasteless powder, used as an anhydrotic in *doses* of one and one-half to three grains (0.096–0.2 Gm.) taken at night.

Sodium and Silver Thiosulphate. *Sodii et Argenti Thiosulphas.*—This double salt may be prepared by dissolving freshly precipitated silver oxide in a solution of sodium thiosulphate and evaporating the solution. It is in the form of minute crystals of the formula $2Na_2S_2O_3 + Ag_2S_2O_3$, very soluble in water, but insoluble in alcohol, and possessing a sweet taste. Its solution, protected from the light, undergoes no change, and, when quite pure, does not discolor the skin or linen. Delioux states that this salt acts locally like silver nitrate, but more mildly: for *gonorrhea*, one or two parts in two hundred of water.

Sodium Anisate. $C_6H_4.OCH_3.COONa + \frac{1}{2}H_2O$. —A white, micro-crystalline, soluble powder, which has been used as a succedaneum for the salicylate as an antipyretic and antirheumatic. *Dose*, five to fifteen grains (0.32–1 Gm.).

Sodium Bisulphite. *Sodii Bisulphis. U. S. VIII. Acid Sodium Sulphite. Leucogen. Sulfite (Bi) de Soude*, Fr. Cod. *Natrium Bisulfurosum. Doppeltschweftigsaures Natron*, G. $NaHSO_3 = 104.08$.—*Sodium bisulphite* is prepared by thoroughly saturating a concentrated solution of sodium carbonate or bicarbonate with sulphurous acid gas, and collecting the crystals which form upon the cooling of the liquid. As found in commerce, it usually contains sodium thiosulphate and sulphate, and is not reliable; even when kept in well-stoppered bottles it will readily lose its crystalline character and the quantity of sulphurous acid gradually diminishes. The bisulphite, under the technical name of leucogen, is largely used in many industries. It serves as bleaching agent in washing wool, and in the steeping of grain, and in preserving meats and vegetable juices, because of its reducing and anti-fermentative character.

Properties.—It was officially described as in "opaque, prismatic crystals, or a granular powder, exhaling an odor of sulphur dioxide, and having a disagreeable, sulphurous taste. Exposed to the air, the salt loses sulphur dioxide, and is gradually oxidized to sulphate. Soluble in 3.5 parts of water, and in 70 parts of alcohol at 25° C. (77° F.); in about 2 parts of boiling water, and in 49 parts of boiling alcohol. When strongly heated, the salt decrepitates, emits vapors of sulphur and of sulphur dioxide, and leaves a residue of sodium sulphate. To a non-luminous flame it imparts an intense yellow color. Its aqueous solution gives an acid reaction with blue litmus paper. On the addition of the hydrochloric or sulphuric acid, an aqueous solution of the salt evolves sulphur dioxide, which is recognized by its odor, and by its blackening a strip of paper dipped into mercurous nitrate T.S. and held over the escaping gas. If 1 Gm. of Sodium Bisulphite be dissolved in 10 Cc. of diluted nitric acid, and the solution heated sufficiently to expel the gases, the liquid should not become turbid (absence of *thiosulphate*). If 1 Gm. of the salt be dissolved in 20 Cc. of diluted hydrochloric acid, and heated sufficiently to expel the sulphur dioxide, the remaining solution, after being restored to its original volume, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If to 50 Cc. of tenth-normal iodine V.S., measured from a burette into a glass-stoppered vial (of about 100 Cc. capacity), 0.25 Gm. of finely powdered crystals of Sodium Bisulphite be added, the solution allowed to stand for about an hour, and shaken at frequent intervals, then the addition of not more than 6.45 Cc. of tenth-normal sodium thiosulphate V.S. should be required to decolorize the solution." *U. S. VIII.*

This salt possesses germicidal properties, which the neutral salt does not, due to the liberation of sulphurous acid. It is used as an antiseptic in *gastric fermentation* and externally in parasitic *skin diseases. Dose*, five to ten grains (0.32–0.65 Gm.).

Sodium Boro-Salicylate. *Sodii Boro-salicylas.* —This is made by heating 125 parts of boric acid, 320 parts of sodium salicylate, and 700 parts of water in a flask until a syrupy liquid is produced; this solidifies on cooling, yielding a white product. It dissolves in water. It is used as an antiseptic and preservative.

Sodium Bromvalerate. *Valerobromin.*—This substance is a mixture of sodium bromide and sodium valerate in molecular proportions and occurs as a crystalline water-soluble mass. It is given in the treatment of nervous maladies, *epilepsy, hysteria, neurasthenia*, etc., in *doses* ranging from thirty to seventy-five grains (2–5 Gm.) daily. It is stated that it should not be administered at all to infants under six months old.

Sodium Caseinate. *N. N. R.* 1917. *Sodii Caseinas. Nutrose. Casein-natrium*, G.—A combination of casein and sodium hydroxide, just enough of the alkali being used to dissolve the freshly precipitated casein. The solution is evaporated *in vacuo*, the dry residue powdered, thoroughly washed with alcohol, and then with ether and dried. A white, amorphous powder, with little odor or taste, insoluble in alcohol and ether, slightly so in cold water, but readily soluble in hot water. It is considered to be a valuable food in intestinal and digestive disturbances, also in *anemia* and *scrofula.*

Sodium Chlorate. *Sodii Chloras. U. S. VIII. Natrium Chloricum. Chlorate de Soude*, Fr. Cod. *Natriumchlorat. Chlorsaures Natron*, G. *Clorato sodico*, Sp. $NaClO_3 = 106.46$.—"It should contain not less than 99 per cent. of pure Sodium Chlorate [$ClO_2.ONa$]. This salt should be kept in well-stoppered bottles, and *great caution should be observed* in handling it, as dangerous explosions are liable to occur when it is heated, or subjected to concussion or trituration with organic substances (cork, tannic acid, sugar, etc.), or with sulphur, antimon sulphide, phosphorus, or other easily oxidizable substances." *U. S. VIII.*

This salt, while manufactured on a large scale for use in the textile industries by the method described under *Potassii Chloras*, is sometimes prepared on a small scale by Whittstein's process, which consists in first preparing sodium bitartrate by adding a strong solution containing 9.5 parts of tartaric acid to a hot aqueous solution of 9 parts of sodium carbonate. The hot solution is mixed with one in which 8 parts of potassium chlorate have been dissolved. Potassium bitartrate separates, while sodium chlorate remains in solution. The filtered solution is evaporated and crystallized. If desired of absolute purity, it may be recrystallized from an alcoholic solution. Owing

to the facility with which this salt parts with its oxygen, the official cautionary direction should be borne in mind.

It occurs in "colorless, transparent crystals (principally cubes with tetrahedral facets), or a crystalline powder; odorless, and having a cooling, saline taste. Permanent in dry air. Soluble in about 1 part of water, and in about 100 parts of alcohol at 25° C. (77° F.); in 0.5 part of boiling water, and in about 40 parts of boiling alcohol; also soluble in about 5 parts of glycerin. When heated, the salt melts, then gives off oxygen (about 45 per cent. of its weight), and finally leaves a residue of sodium chloride, readily soluble in water, and yielding, with silver nitrate T.S., a white, curdy precipitate, insoluble in nitric acid. To a non-luminous flame it imparts an intense yellow color. An aqueous solution of Sodium Chlorate (1 in 20) is neutral to litmus paper. When a crystal of the salt is dropped into hydrochloric acid, the liquid assumes a deep greenish-yellow color, and emits the odor of chlorine. A saturated, aqueous solution should not be rendered turbid by sodium bitartrate T.S. (limit of *potassium*). The aqueous solution of the salt (1 in 20), upon the addition of 1 Cc. of ammonium sulphide T.S., should not develop a dark coloration (absence of *lead, copper*, etc.)." *U. S. VIII.*

Sodium chlorate has medicinal properties similar to those of potassium chlorate, while its greater solubility permits the use of stronger solutions. According to Brissaud, when given in daily doses of more than two drachms it is apt to produce albuminuria. In overdose it would probably cause symptoms not distinguishable from those caused by potassium chlorate poisoning. *Dose*, five to fifteen grains (0.32–1.0 Gm.).

Sodium Dithiosalicylate. $S(C_6H_3(OH)CO\,ONa)_2$. *Dithion I* and *II.*—These are two isomeric salts separable by means of sodium chloride solution, the dithion I being insoluble in the latter solution. Dithion I is a yellowish-white, amorphous, soluble powder employed mostly in veterinary practice as a dusting powder of antiseptic value. The dithion II is used like sodium salicylate as an antirheumatic and antipyretic, free it is said, from secondary action. *Dose*, thirty to sixty grains (2–4 Gm.).

Sodium Ethylate. *Sodii Ethylas. Ethylate of Sodium. Caustic Alcohol.* C_2H_5ONa.—This preparation was introduced by B. W. Richardson of England, as a caustic. He makes it by adding sodium in small pieces gradually to absolute alcohol, kept at a temperature of 10° C. (50° F.); hydrogen is evolved, and when, owing to the formation of the ethylate, the reaction slackens, the liquid is to be carefully heated to 37.7° C. (100° F.). Sodium is then cautiously added until the reaction ceases; the liquid is cooled to 10° C. (50° F.), and the same quantity of absolute alcohol added as was used in the beginning. (*P. J.*, 1878, 485.) *Sodium ethylate* is a white powder, frequently having a brownish tinge, dissolving in water with a hissing sound, having the property of splitting into alcohol and sodium hydroxide upon contact with even a small quantity of water or moist living tissue:

$$C_2H_5ONa + H_2O = C_2H_5OH + NaOH$$

Sodium ethylate does not appear to be of any value as an internal remedy. When, however, it comes in contact with moist tissue, owing to the liberation of its sodium, it acts as a very speedy and powerful caustic. It should always be used in alcoholic solution, and applied by means of a glass rod. It is said to cause very little pain, and has been specially employed for the destruction of *nævi*. (*L. L.*, Nov., 1878.) A *solution of sodium ethylate* was official in the Br., 1898, under the title *Liquor Sodii Ethylatis*. It was prepared as follows: "Sodium, clean and bright, 22 *grains* (Imperial) or 1 gramme; Absolute Alcohol, 1 *fl. ounce* (Imp. meas.) or 20 mils. Cautiously dissolve the Sodium in the Absolute Alcohol contained in a flask, the latter being kept cool by a stream of cold water." *Br.*, 1898.

It is described as "a colorless liquid of syrupy consistence, becoming brown by keeping. Specific gravity 0.867. When slightly heated it boils and gives off alcoholic vapors, leaving a white residue which, on being strongly heated, becomes charred. If the white residue be mixed with *water* and heated, it yields ethylic alcohol, and the solution, on evaporation, leaves a white residue consisting almost wholly of caustic soda. This solution should be recently prepared. It contains 18 per cent. of the solid substance, C_2H_5ONa." *Br.*, 1898. It may be made more conveniently by dissolving twenty grains of sodium ethylate in 80 grains of absolute alcohol. It is used solely as a caustic, and is said to produce very little pain. It should not be allowed to come in contact with water. Richardson states that it should always be kept in glass-stoppered bottles, in a cold place, as he has known it to explode when placed in warm situations. Gamberini and Monari (*R. T.*, 1892) assert that the 20 per cent. liniment made with olive oil, well rubbed in daily, will usually cure *psoriasis* in twenty days, and that the 10 per cent. aqueous solution is very valuable in the treatment of *lupus erythematosus*, applied after curetting.

Sodium Formate. *Sodii Formas. Ameisensaures Natrium*, G. $HCO_2Na + H_2O$.—Prepared by neutralizing formic acid with sodium carbonate. It occurs in colorless, rhombic prisms, which are inodorous, and have a saline, bitter taste. Sodium formate is very deliquescent and dissolves freely in water. *Dose*, one-half to three grains (0.032–0.2 Gm.).

Sodium Fructosate. $C_6H_{11}NaO_6$.—This substance forms a yellowish, extremely hygroscopic powder, and is employed in place of the usual physiological salt solution for sustaining the heart action. It has been stated that it gives a better action when about 50 per cent. calcium saccharate is added to it and the two dissolved in normal salt solution.

Sodium Metaborate. *Antipyonin.* $NaBo_2 + H_2O$.—*Sodium metaborate* is made by boiling borax and boric acid in water. It is also called *sodium tetraborate*. It occurs as a fine, white powder, greasy to the touch, freely soluble in water. This salt is non-poisonous, devoid of caustic action, and markedly antiseptic. It is probably therapeutically equivalent to borax, but has been especially recommended in a 2 to 50 per cent. solution, or blown in as a powder, by Jaenicke and by Kafemann in *acute* and *chronic otorrhea*. Roland attributes extraordinary effects to its insufflation in *keratitis, conjunctivitis*, and other inflammatory eye conditions.

Sodium Methyl Arsenate. *Di-sodium Methyl Arsenate. Sodii Methylarsenas.* $(OAsCH_3O_2Na_2 + 5H_2O.)$—This arsenic preparation occurs as a crystalline powder containing 27.37 per cent. arsenic, easily soluble in water and less so in alcohol. It is precipitated by alkaloids, with mercuric chloride it gives a reddish precipitate, and with

copper sulphate a green precipitate. It appears to be about equivalent in its physiological and therapeutic effects to sodium cacodylate (see page 1019), over which the advantage is claimed that it does not impart a garlicky odor to the breath that is characteristic of the cacodylates. The *dose* is from one-third to one grain (0.021–0.065 Gm.). It is also sold under various trade names, as *arrhenal, arsynal, neosarsycodile, stenosine,* etc.

Sodium Naphthol. *Naphthol Sodium.—β-Naphthol sodium (microcidine),* a white powder easily soluble in water, used as a non-caustic, non-poisonous antiseptic, said to be much stronger than phenol.

Sodium Nitrate. *Sodii Nitras. U. S. VIII. Nitrate of Soda. Cubic Nitre. Chili Saltpeter. Nitras (Azotas) Sodicus. Nitrum Cubicum. Azoate (Nitrate) de Soude,* Fr. Cod. *Nitre cubique Nitrate de Chili,* Fr. *Natrium Nitricum,* P. G. *Natriumnitrat. Chilesaltpeter,* G. *Nitrato di sodio,* It. $NaNO_3 = 85.01$.—"It should contain not less than 99 percent. of pure Sodium Nitrate [$NO_2.ONa$], and should be kept in well-stoppered bottles." *U. S. VIII.* This salt is imported from South America, where it is found naturally, especially in the desert of Atacama, forming beds of vast extent. The nitrate deposits have been found uniformly through a zone 250 geographical miles in length north to south, and two geographical miles in width east to west. It was estimated that the nitrate beds contained the enormous quantity of 99,031,525 tons. The salt has been found also largely in Brazil, in the province of Bahia, near the river San Francisco. (*A. J. P.,* Nov., 1861, 502.) For an account of the sodium nitrate deposits of Chili, see *Potassii Nitras.* The crude salt is in saline lumps, rather soft and friable, and damp on the surface. Its varieties are classified, according to their color and state of aggregation.

The importations of sodium nitrate into the U. S., in 1915, were 575,371 tons, valued at $16,280,510 and in 1916 were 1,072,833 tons, valued at $32,129,926.

"*Caliche,*" as the crude mineral is called, contains from 48 to 75 per cent. of sodium nitrate, from 20 to 40 per cent. of sodium chloride, and smaller amounts of sodium sulphate, calcium sulphate, potassium nitrate, and potassium and sodium iodate (from 0.059 to 0.175 per cent. of iodine). Occasionally calcium borate, associated with sodium borate, is found under the beds of the nitrate.

Sodium nitrate, when pure, is in "colorless, transparent, rhombohedral crystals, odorless, and having a cooling, saline, and slightly bitter taste. Hygroscopic in moist air. Soluble in about 1.1 parts of water, and in about 100 parts of alcohol at 25° C. (77° F.); in 0.6 part of boiling water, and 40 parts of boiling alcohol. When heated to 312° C. (593.6° F.), the salt melts without decomposition. At a higher temperature it evolves oxygen, and is reduced to nitrite. When Sodium Nitrate is heated with charcoal, the mixture deflagrates. To a non-luminous flame it imparts an intense yellow color. Its aqueous solution is neutral to litmus paper. If the aqueous solution be mixed in a test-tube with a drop of diphenylamine T.S., and sulphuric acid be carefully poured in, so as to form a separate layer, a deep blue color will appear at the line of contact. The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If to 10 mils of the aqueous solution of the salt (1 in 20) 1 mil of chloroform be added, and then chlorine water which has been diluted with an equal volume of water be introduced, drop by drop, with agitation, the chloroform should remain free from any violet tint (absence of *iodine*)." *U. S. VIII.* Like potassium nitrate, it deflagrates when thrown on the fire, but it is distinguished by giving rise to an orange-yellow flame, and by the rhomboidal shape of its crystals, those of niter being long six-sided prisms. It evolves ruddy fumes when warmed in a test-tube with sulphuric acid and copper wire. This salt has been praised as a remedy in *dysentery* (see 15th ed., *U. S. D.*), in the *dose* of from half an ounce to an ounce (15.5–31 Gm.) in the course of the day in dilute solution, but is at present very rarely, if ever, used in practical medicine.

Sodium Nitroferrocyanide. *Sodium Nitroprusside. Sodii Nitroferrocyanidum.* $Na_2Fe(CN)_5NO$.—This is one of the interesting series of salts, discovered py Playfair, called *nitroprussides,* which are produced, for the most part, by saturating *nitroferrocyanic acid,* formed by the action of nitric acid in potassium ferrocyanide, with different bases. The sodium salt is best obtained by the process of A. Overbeck, as follows: Dissolve four parts of powdered potassium ferrocyanide, contained in a flask, in five and a half parts of commercial nitric acid, diluted with an equal weight of water. After the action is completed, which generally occupies about ten minutes and is accompanied by a copious evolution of gases, heat the resulting coffee-brown liquid in a water bath, until a drop of it gives a dingy green instead of a blue precipitate with a solution of ferrous sulphate. Then allow the liquid to cool; whereupon the larger part of the potassium nitrate generated will be deposited in crystals. Pour off the green mother liquor from these, and separate the remaining potassium nitrate by repeated concentrations. Next, neutralize the liquid, while heated in a water bath, with sodium carbonate, taking care to add the carbonate so long as a pure blue precipitate is produced. Lastly, filter the solution, and set it aside for the formation of crystals, which must be washed with water, and dried between blotting paper. The salt is in the form of large, ruby-colored, prismatic crystals, resembling those of potassium ferricyanide. It is soluble in two and a half parts of cold water, and in less quantity of hot water. Its solution, exposed to sunshine, is decomposed, with evolution of nitric oxide gas, and deposition of Prussian blue, at the same time acquiring a green color. Sodium nitroprusside, as well as the other soluble nitroprussides, is a most delicate test for alkaline sulphides, with which it produces a violet color. It is used also as a test for acetone in urine and in several tests for the detection of formaldehyde.

Sodium Oleate. *Sodii Oleas. Eunatrol. N. N. R.* 1917.—*Sodium oleate* may be made by dissolving 10 parts of sodium hydroxide in alcohol and adding the solution to 100 parts of oleic acid and carefully evaporating the soap which is formed to dryness. It is a whitish mass or a white powder, dissolving freely in water and alcohol. It was at one time believed to be useful in cases of *gall stone. Dose,* from fifteen to forty grains (0.9–2.6 Gm.) daily in capsules.

Sodium Paracresotate. $C_6H_3(CH_3)-(OH)CO ONa$.—An analogue of sodium salicylate obtained through the action of phenol on paracresol alkali. *Sodium metacresotate* and *sodium orthocresotate*

are found in commerce. It forms an inodorous, colorless, bitter, soluble powder used in *gastric catarrh, acute rheumatism,* and *typhoid fever* in *doses* of two to twenty grains (0.13–1.30 Gm.).

Sodium Phenolsulpho-ricinate. *Sodii Phenolo-sulpho-ricinas* (25 per cent.).—This phenol compound has been highly recommended as a local application in *laryngeal tuberculosis* and *papilloma;* also in *ozena.* In the latter disease the pituitary membrane and the nasal ducts are first cleansed and subjected to vigorous daily frictions with the aid of a sound padded with wadding steeped in a solution of *sodium phenolsulphoricinate* (1 to 2 or 3 parts of water).

Sodium Phenyl Propiolate. *Theranol. Thermiol.* $C_6H_5.C : C.COONa$.—This differs in its chemical formula from sodium cinnamate in that it contains two atoms less of hydrogen. It is marketed in the form of a 25 per cent. solution, to which has been given the trade name of *thermiol.* This solution is employed as an inhalation in the treatment of laryngeal and pulmonary *tuberculosis.* It should be diluted to make 1 per cent. to 4 per cent. solution of the salt. (See Bulling, *M. M. W.,* 1905.)

Sodium Pyrophosphate. *Sodii Pyrophosphas. U. S. VIII. Natrium Pyrophosphoricum. Pyrophosphate de Soude,* Fr. Cod. *Natriumpyrophosphat,* G. *Pirofosfato sodico,* Sp. $Na_4P_2O_7 + 10H_2O = 446.24$.—"It should contain, in an uneffloresced condition, not less than 99 per cent. of pure Sodium Pyrophosphate $[(PO)_2O.(ONa)_4 + 10H_2O]$, and should be kept in well-stoppered bottles." *U. S. VIII.* This salt which was recognized by the U. S. VIII is prepared by heating sodium phosphate in a suitable vessel to redness. When sodium phosphate is subjected to a temperature of 44° C. (11.2° F.), it melts in its water of crystallization; if the heat be increased to 100° C. (212° F.), all the water will be dispelled, and but 40 per cent. of the original weight remain; at 300° C. (572° F.) it is converted into the tetrabasic phosphate or pyrophosphate. By dissolving this residue in water, filtering and crystallizing, the salt may be obtained.

It occurs in "colorless, transparent, monoclinic prisms, or a crystalline powder; odorless, and having a cooling, saline, and feebly alkaline taste; slightly efflorescent in warm air. Soluble in about 11.5 parts of water at 25° C. (77° F.), and in 1.1 parts of boiling water; insoluble in alcohol. When heated to 100° C. (212° F.), the salt loses its water of crystallization (40.35 per cent.) without previous fusion. At a higher temperature it fuses, forming a transparent liquid, which, on cooling, solidifies to a crystalline mass." *U. S. VIII.* An aqueous solution is feebly alkaline to litmus and to phenolphthalein. It may be distinguished from the orthophosphates by the facts that it gives a precipitate with silver nitrate T.S., and does not with ammonium molybdate even when heated. The action of this salt upon the human economy is probably that of the phosphate. It has been highly recommended for removing ink stains from colored cotton fabrics. It is said to remove the stains slowly without affecting the other colors.

Sodium Selenite. *Sodii Selenis.* Na_2SeO_3.—A white powder which freely dissolves in water. The aqueous 2 per cent. solution of *sodium selenite* stains bacteria red by the precipitation of *metallic selenium,* and has been highly recommended for the purpose of microscopic staining.

Sodium Silicate. *Sodii Silicas. Soluble Glass.* $Na_2SiO_3 + H_2O$.—*Sodium silicate* is made by fusing one part of silica, fine sand, or powdered flint, and two parts of dried sodium carbonate, mixed in powder, in an earthenware crucible, and pouring out the fused mass on a stone slab to cool. This is pulverized, and treated with boiling water, to dissolve the soluble part. The solution is filtered and concentrated, so as to form crystals on cooling. These are then purified by dissolving them in water heated to 37.7° C. (100° F.), filtering the solution, and concentrating it so that it may recrystallize. The commercial solution of sodium silicate usually contains about 20 per cent. of silica and 10 per cent. of soda. In contact with acids the solution undergoes decomposition. It is employed in fixing fresco colors by the process of stereochromy, as a cement in the manufacture of artificial stone, and as an addition to soaps, constituting the so-called *silicate soaps.* Sodium silicate has been employed as an antiseptic, in the treatment of chronic *urethritis, vaginitis,* etc., but R. Löwenhaupt asserts that when pure it is not antiseptic, any powers which it may seem to have being dependent upon the presence of free alkali in it. Sodium silicate has been suggested as a remedy in *pulmonary tuberculosis,* and Scheffer (*K. T. W.,* 1908) asserts that it has an influence upon mineral metabolism, and is a useful remedy in *arteriosclerosis.* He recommends a *dose* of from twenty-four to forty-five minims (1.6–3.0 Gm.) of the *liquor sodii silicatis* three times a day. It should be given well diluted. Zeller (*M. M. W.,* 1912) recommends the internal use of a mixture of sodium and potassium silicate in the treatment of *external cancers* in conjunction with an arsenical paste. The mixture he employed contained three-quarters of a grain (0.048 Gm.) of each of the silicates, and he gave it three times a day.

Under the name of *Liquor Sodii Silicatis* the U. S. Pharm., 1890, formerly recognized the solution of sodium silicate, describing it as "a semi-transparent, almost colorless, or yellowish, or pale greenish-yellow, viscid liquid, odorless, having a sharp, saline, and alkaline taste, and an alkaline reaction. Specific gravity, 1.300 to 1.400 at 15° C. (59° F.). A drop of the Solution, when held in a non-luminous flame, imparts to it an intensely yellow color. If a portion of the Solution, largely diluted with water, be supersaturated with nitric acid, a gelatinous or pulverulent, white precipitate of silic hydrate will be produced." The solution is used in the preparation of mechanical dressings by the surgeon in the same class of conditons for which plaster of paris is employed.

Sodium Silico-Fluoride. *Sodii Silico-fluoridum.* Na_2SiF_6.—When gaseous SiF_4, generated by the action of sulphuric acid upon fluorspar in the presence of broken glass, is passed into water, hydrogen silico-fluoride, H_2SiF_6, is formed. This acid, when neutralized by sodium hydroxide or carbonate, will yield the sodium salt. It is difficultly soluble in water. It is asserted for the *silico-fluoride of sodium* that its solution, *salufer,* is practically non-toxic and powerfully antiseptic. The powder is a strong irritant or a mild caustic. The solution affects steel instruments. Bokenham, in experiments upon bacteria, found that in order to kill them it was necessary for the solution to be at least as strong as one to seven hundred and fifty parts, and that the drug has toxic properties, 0.05 Gm. of it causing prolonged nausea, great slowing of pulse, and reduction of arterial pressure.

Sodium Stearate. *Sodii Stearas.* $NaC_{18}H_{35}O_2$.

—The pencils of this substance, which have been recommended by T. G. Unna for use in *sycosis* and other parasitic skin diseases, are made as follows: Sodium stearate, 6 Gm. (90 gr.); glycerin, 2.5 Gm. (30 min.); alcohol, sufficient to make 100 Gm. (4 fl. oz.). The affected part should be rubbed with the pencil five or six times daily.

Sodium Succinate. *Sodii Succinas. N. N. R.* 1917. $Na_2C_4H_4O_4 + 6H_2O$.—White crystals freely dissolving in water. *Sodium succinate* has been highly commended by Ch. F. Hope for *catarrhal jaundice. Dose*, fifteen to twenty grains (1.0–1.3 Gm.) every three or four hours.

Sodium Sulphobenzoate. *Sodii Benzosulphonas. Sodium benzosulphonate.* $C_6H_4(NaSO_3)COONa$.—Heckel (*C. R. A. S.*, cv, 896) asserts that *sodium sulphobenzoate* is a non-poisonous antiseptic, superior to phenol, and equal to mercurial solution in the antiseptic treatment of wounds; strength of solution about fifty grains in a quart. It has been employed by L. Webster Fox in subconjunctival injections.

Sodium Sulphocyanide. *Sodium Sulphocyanate. Sodium Rhodanide. Sodium Thiocyanate.* NaSCn.—Bentley and Le Roy have found that this salt had the power of rendering soluble insoluble salts of calcium and magnesium and have suggested its use in the treatment of *arterial sclerosis* and *urinary calculus.* They administered it in *doses* up to one grain (0.065 Gm.). The remedy has also been suggested as a substitute for the iodides, especially in the treatment of chronic nervous conditions.

Sodium Sulphomethylate. *Sodii Methylsulphonas. Sodium Methylsulphonate.* $CH_2(OH)SO_3Na + H_2O$.—According to Rabuteau, this salt in 240 grain (15.5 Gm.) *doses* produces catharsis without cramp. (*A. J. P.*, 1880, 220.)

Sodium Sulphoricinoleate. *Sodium Sulphoricinate. Oleite.*—This substance may be prepared from castor oil by treating it with sulphuric acid at a low temperature, when a compound of sulphuric and ricinoleic acids is formed. The free sulphuric acid being removed by washing, and any unchanged oil by ether, the resulting sulphoricinoleic acid is then neutralized by sodium hydroxide, the finished product being a brown transparent, jelly-like liquid, with little odor, having an acrid taste, and soluble in water, alcohol, chloroform, and essential oils. It has remarkable solvent powers, dissolving phosphorus, iodine, phenol, resorcinol, naphthalene and many other medicinal substances. The phenol solution, often incorrectly called phenol sulphoricinate is described below.

According to the experiments of Fred B. Kilmer (*Proc. A. Ph. A.*, 1890; *P. J.*, xx, 1890), its action upon mucous membranes, healthy and diseased skins, *cuts, burns*, etc., is highly soothing, and it may be taken internally or freely absorbed through the skin without danger. It would appear, therefore, to afford an excellent basis for ointments; but as productions made with it are very sticky, and often liable to harden, it is commonly best used by rubbing the substance with oleite, and then adding 50 per cent. of fatty base.

A mixture of sodium sulphoricinate and phenol is sold under the title *Phenolum Natro-sulphoricinicum* (*phenol sulphoricinate*). It is a yellowish, syrupy liquid, containing 25 per cent. of phenol and 75 per cent. of sodium sulphoricinate. The liquid itself mixes in all proportions with water, and has been especially commended as a local application in various *diseases of the skin* and in *tubercular* and other *ulcerations of the mucous membranes.* First, recommended by T. Heryng (*Th. M.*, 1896) as a local caustic application to *papilloma* and *ulcers* in the nasal and laryngeal passages, or diluted in various forms of chronic inflammation of the mucous membrane of the nose and larynx. These statements have been confirmed by various laryngologists. Prezedborski finds it of very great service both in *rhinitis atrophica* and *hypertrophica.* Berlioz (*B. G. T.*, 1890) especially recommends it in *diphtheria.* The 20 per cent. aqueous solution is to be applied locally to the throat four times a day and once or twice in the night. (*S. M.*, 1892.)

Sodium Sulphosalicylate. *Sodii Salicylsulphonas.* $C_6H_3(OH)\langle^{COOH}_{SO_3Na}$. *Sodium Salicylsulphonate.*—*Salicylsulphonic acid*, made by acting on salicylic acid with sulphuric acid, is partly neutralized with sodium carbonate. It occurs as a white crystalline powder, soluble in twenty-five parts of water, insoluble in alcohol and ether. It is used as a substitute for sodium salicylate. It is less powerful than the latter, but free from its after effects. *Dose*, ten to thirty grains (0.65–2.0 Gm.).

Sodium Sulphovinate. *Sodium Ethylsulphate.* $C_2H_4(OH)SO_3Na + H_2O$.—This salt occurs as a white, granular powder or in hexagonal tabular crystals, according to the method of its preparation. Its taste is cooling and rather aromatic, nearly destitute of bitterness. It is very deliquescent, and is soluble in 0.7 part of water.

When sulphuric acid is added to alcohol the temperature rises at once, and a certain proportion of sulphovinic acid is formed, but, as water is at the same time developed, the reaction is soon arrested by the dilution of the mass. The first practical method of overcoming the difficulty was afforded by the process of Limousin. Nineteen and a half ounces (avoirdupois) each of pure sulphuric acid, sp. gr. 1.715, and of concentrated alcohol, about 96°, are slowly introduced by means of two funnels (one for the alcohol and the other for the acid) into a third funnel arranged in a flask plunged into a freezing mixture or kept in a current of cold water, the flow of the two liquids into the flask being so regulated as to keep the alcohol in excess. The mixture is kept for four to five days at a temperature of from 20° C. (68° F.) to 25° C. (77° F.), then diluted with from nine to ten pints of distilled water, and carefully saturated with somewhat less than forty-eight ounces of pure barium carbonate in solution. When the point of saturation has been attained, the liquid is left to deposit the barium sulphate, and afterwards filtered. The solution of barium sulphovinate so obtained is saturated with between twenty-seven and twenty-nine ounces of pure sodium carbonate dissolved in four liters of distilled water. When no more precipitate is formed by the addition of the alkaline solution, and the liquid is neutral to test paper, the transformation of the barium sulphovinate into *sodium sulphovinate* is complete. The liquor, decanted and filtered, is evaporated in a water bath until it has the sp. gr. 1.33, and left to crystallize. The drained crystals are dried in an oven. For additional methods of making the salt, see *U. S. D.*, 19th ed., p. 1653.

Sodium sulphovinate is said to be a mild although active cathartic. According to Rabuteau, five drachms (19.4 Gm.) of it dissolved in three glasses of water will generally produce in the adult four or five liquid stools without pain. The *dose* for children is from two to three drachms (7.7–

11.6 Gm.). The pleasantness of its taste and action would render it a favorite purgative were it not for its high price and the difficulty of preserving it, all of the sulphovinates having a great tendency on exposure to the air to break up into alcohol and a salt of sulphuric acid.

Sodium Tartrate. *Sodii Tartras.* $Na_2C_4H_4O_6$. $2H_2O = 230.06$.—This salt, in crystals, has been recommended by Delioux as an agreeable purgative, almost without taste, and acting with a power equal to that of the magnesium sulphate in the *dose* of ten drachms. The *soda powders*, so much used in the United States, form an extemporaneous sodium tartrate, somewhat aërated with carbon dioxide. A *solution of sodium tartrate* has been used as a substitute for solution of magnesium citrate. It may be made by dissolving six drachms of tartaric acid in two fluidounces of water, and seven and a half drachms of sodium bicarbonate in seven fluidounces of water, mixing the solutions gradually and filtering; the filtrate should be poured into a strong twelve fluidounce bottle and two fluidounces of lemon syrup added slowly, so that it will sink to the bottom of the bottle without mixing very much with the solution; eighty grains of tartaric acid are to be added without agitating the bottle, which is to be corked at once securely and set aside in a cool place. The bottle is to be shaken just before the contents are administered.

Sodium Tellurite. Na_2TeO_3.—*Sodium tellurite* is a white powder sparingly soluble in water. The aqueous 2 per cent. solution of sodium tellurite stains bacteria black by the precipitation of *metallic tellurium*, and has been highly recommended for the purpose of microscopic staining.

Sodium Thiophene Sulphonate. $NaC_4H_3S_2O_3 + H_2O$.—A white powder containing about 33 per cent. of sulphur. It is soluble in water and is used either in a 5 to 10 per cent. solution or ointment in the treatment of *skin diseases*.

Sodium Valerate. *Sodii Valerianas. Sodii Valeras.* C_4H_9COONa.—This salt was dismissed from the U. S. Pharmacopœia in 1870, and from the British Pharmacopœia in 1898. For a process for preparing it, see *U. S. D.*, 19th ed., p. 1654. *Sodium valerate* is a deliquescent, very soluble salt, in snow-white masses, having the disagreeable odor of valeric acid, and a taste at first styptic, but afterwards sweetish. When heated to 140.5° C. (285° F.), it fuses without loss of acid, and upon cooling concretes into a white solid. It is little used medicinally, having been originally introduced into the Dublin Pharmacopœia in 1850 for the sole purpose of forming, by double decomposition, iron, quinine, and zinc valerates. *Dose*, as a nervous stimulant, one to five grains (0.065–0.32 Gm.).

Soja. *Glycine hispida* Maxim. (*Soja hispida* Moench.) *Soy Bean. Soja* or *Sahuca Bean. Miso.* (Fam. *Leguminosæ.*)—*Soja* is an important food plant and forage crop. It is an annual having hairy, trifoliate leaves, inconspicuous, violet-colored flowers, and forms broad legumes containing 2 to 5 seeds. The latter are compressed, spherical and vary from brownish-green to brownish-black. Meissel and Böcker (*A. J. P.*, 1885, 108) give the composition of soja bean as follows: water, 10 per cent.; soluble casein, 30; albumen, 0.5; insoluble casein, 7; fat, 18; cholesterin, etc., 2; dextrin, 10; starch, 5; cellulose, 5; ash, 5; traces of sugar and an amido compound. Stingl and Morawski (*Monatsschrift für Chemie*, April, 1886) have determined the presence in this bean of a ferment said to be one of the most powerful known in its action upon starch, two-thirds of which it converts into sugar and one-third into dextrin. Soja bean has been suggested as a diabetic food, but it contains upwards of 25 per cent. of carbohydrates.

Solanine. $C_{42}H_{75}O_{18}N$.—A physiologically active substance obtained from the sprouts of *Solanum tuberosum* L. (potato), and other *Solanaceæ*. It is classed both as a glucoside (because of its being decomposable into glucose), and also as an alkaloid (because of its basic properties). *Solanine* is in the form of a white, opaque powder, or of delicate acicular crystals, somewhat like those of quinine sulphate, though finer and shorter. It is inodorous, of a bitter taste, fusible at from 112.7° to 115.5° C. (235°–240° F.), decomposing at a slightly higher temperature with an odor of caramel, a sublimate of *solanidine* forming. It is scarcely soluble in water, soluble in alcohol and ether, and capable of neutralizing the acids. It is distinguished by the deep brown or brownish-yellow color which iodine imparts to its solution, and by its reaction with sulphuric acid, which becomes first reddish-yellow, then purplish-violet, then brown, and, lastly, again colorless, with the deposition of a brown powder. This test is said not to be interfered with by the presence of morphine. (*A. J. P.*, 1873, 484.) The salts which solanine forms with acids are mostly amorphous in character. The oxalate, chromate, and phosphate form crystalline crusts. The acid sulphate is said to be very stable, and is not decomposed by water even on heating, in contradistinction to the neutral salt. It is amorphous and very bitter.

The physiological action of solanine is very similar to that of the saponins. Perles (*A. E. P. P.*, 1889, xxvi) found that when mixed with the blood outside of the body it caused rapid coagulation with destruction of the blood corpuscles. In the frog it produced a centric paralysis, with later paralysis of the heart. In mammals it produced excitement, with tremors, followed by central paralysis, collapse, and death in deep coma, preceded by a fall of temperature which is so great as to be almost characteristic. Vomiting and diarrhea were frequently observed, and the urine contained albumin and often hemoglobin. After death inflammation of the gastro-intestinal mucous membranes, and also a parenchymatous and even hemorrhagic nephritis were found. According to Capparoni (*B. G. T.*, May, 1888), minute doses of solanine, while diminishing the rapidity of the heart's action, increase at the same time the arterial pressure.

In the researches of Max Perles, the action of *solanidine* was very similar to that of solanine, the chief difference between the two being that solanine is a violent local irritant, while solanidine seems free from local irritant properties.

Solanine has been used with asserted benefit by Capparoni (*B. G. T.*, May, 1888) and others, as an antispasmodic remedy in *asthma*, *bronchitis* and *cystitis*. It is also attributed with a sedative action on the central nervous system, and has been used by Capparoni in the treatment of ataxic pains. Waugh (*J. A. M. A.*, 1906) asserts that it is of great service in *epilepsy*.

Schmiedeberg (*A. E. P. P.*, 1899, xxxvi, 361) describes an epidemic of solanine poisoning from sprouted potatoes in which the symptoms were headache, colic, vomiting, diarrhea, dilated pupils,

first accelerated, then slowing of the pulse, mental confusion and sometimes unconsciousness.

The *dose* of solanine, as given by different writers, varies widely, probably because of varying degrees of purity of the drug employed.

Waugh states that of the pure alkaloid, the proper *dose* is one-twelfth of a grain (0.005 Gm.), but other writers have given much larger amounts.

Solanum.—The genus *Solanum* contains a number of species which are possessed of active physiological properties and some of which have been used to a considerable extent in medicine.

S. carolinense L. *Horse Nettle. Sand Brier. Poisonous Potato. Apple of Sodom.*—Under the name of *Solanum* the N. F. IV has made the berries of *S. carolinense* official and has introduced fluidextract of solanum made with a menstruum of two volumes of alcohol and one volume of water.

"The air-dried ripe fruit of *Solanum carolinense* Linné (fam. *Solanaceæ*)." *N. F. IV.*

"Globose, slightly depressed, somewhat shriveled and wrinkled in drying, from 0.8 to 2 cm. in diameter, orange-yellow, glabrous, fleshy, two-celled, many-seeded, calyx and pedicel usually persistent; calyx stellate pubescent, deeply five-lobed, the lobes ovate or ovate-lanceolate, acuminate and enclosing half or more of the berry; seeds orbicular, flat, yellow, smooth, shining. Odor pepper-like; taste bitter and acrid.

"Solanum yields not more than 6 per cent. of ash." *N. F. IV.*

This is a coarse perennial weed growing in waste sandy ground in the United States as far west as Iowa and as far south as Florida, and yields an orange-yellow berry which is said to be the most active part of the plant. For study of microscopic structure, see *A. J. P.*, vol. lxix. It has been examined by G. A. Krauss (*A. J. P.*, 1890, 601, and 1891, 65 and 216) and Harry Kahn (*A. J. P.*, 1891, 126). Krauss found two active principles corresponding probably to *solanine*, $C_{42}H_{75}NO_{15}$, and *solanidine*, $C_{41}H_{71}NO_2$, together with a characteristic organic acid to which he gives the name *solanic acid*. J. U. Lloyd believes that the alkaloid in this plant is not identical with solanine, and proposes to call it *solnine*. (*A. J. P.*, 1894, 61, and 1897, 76, 89, 108.) E. Q. Thornton (*T. G.*, xii, 1896) finds that in frogs this solanum produces stupor with tetanic spasms, not prevented by section of the cord. It is said to have long been used by the negroes of the South in the treatment of the so-called falling sickness, and in 1889 it was recommended by J. L. Napier as of value in *epilepsy*. H. C. Wood has found that, although when given by itself its usefulness is very limited, as an adjuvant to the bromides it lessens the size of the doses necessary to keep the convulsions in check. Not less than a fluidrachm (3.75 mils) of the fluidextract should be given three times a day. No unpleasant effects have been produced by it. The N. F. recognizes a fluidextract (see Part III).

S. aculeatissimum Jacq., known as *Apple of Sodom*, is indigenous to Brazil; the fruit yields traces of *solanine*.

S. bacciferum (?), of Jamaica, yields the so-called *Susumber berries*, which are habitually used as fruit by the natives, but Manners has recorded in the *Ed. M. J.*, 1867, fatal poisoning by these berries, death being preceded by dilated pupils and collapse. It is probable, however, that the berries were not true susumber berries but were the product of some other species of solanum.

S. Chenopodium F. Muell.—In this plant, which is a native of Queensland, C. E. Sage has found the alkaloid *solanine*. According to E. B. Ormerod the plant is useful in the treatment of *dysentery*. (*P. J.*, lxviii, 1902.)

Under the English title *Bittersweet* the *N. F. IV* recognizes "The dried stems and branches of *Solanum Dulcamara* Linné (Fam. *Solanaceæ*)." N. F. The Latin title is *Dulcamara*, the synonyms *Stipites Dulcamaræ*, *Tiges de Douce-amère* (*de Morelle grimpante*), *Douce amère*, Fr. *Bittersüss*, *Bittersüss-Stengel*, *Alpranken*, G. *Dulcamara*. *Dulcamara* is a climbing shrub with a woody branching stem and purplish, cymose flowers, with lemon-yellow anthers. The bright scarlet berries remain after the falling of the leaves. The plant grows in wet places and around dwellings and is common to Europe and North America, and in the United States grows from New England to Ohio. All portions of the plant are very active. Fatal results from the eating of the berries by a child have been recorded. (*P. J.*, 1861.) For medicinal purposes the plant should be gathered in the autumn after the fall of the leaf, and the extreme twigs should be selected. That grown in high and dry situations is said to be the best.

It is described in the N. F. as "In short sections about 5 mm. or less in thickness, cylindraceous, somewhat angular, longitudinally striate, more or less warty, usually hollow in the center; bark thin, externally pale greenish, or light greenish-brown, glabrous, marked with alternate leaf scars, internally green, the greenish or yellowish wood occurring in one or two concentric rings. Odor slight; taste bitter, afterwards sweet.

"The powder is greenish-yellow and, when examined under the microscope, exhibits tracheæ up to 0.05 mm. in diameter and with bordered pores; lignified wood fibers with few pores; non-lignified bast fibers with walls up to 0.02 mm. in thickness; fragments of cork cells; few, simple, unicellular hairs up to 0.8 mm. in length, and with the lumina distinct in the lower portions only; few starch grains, spheroidal, up to 0.012 mm. in diameter; sphenoidal crystals of calcium oxalate numerous, up to 0.007 mm. in length.

"Bittersweet yields not more than 6 per cent. of ash." *N. F. IV.*

The dried twigs are inodorous, though the stalk in the recent state emits, when bruised, a peculiar, rather nauseous odor. Their taste, which is at first bitter and afterwards sweetish, have given origin to the name of the plant.

Boiling water extracts all their virtues. These are supposed to depend, at least in part, upon the alkaloid *solanine*. Wittstein (1852) supposed another alkaloid, *dulcamarine*, to be present, but Geissler (1875) showed that this substance was a glucoside, and not an alkaloid, yielding on decomposition with dilute acids *dulcamaretin* and sugar. He assigned the formula $C_{22}H_{34}O_{10}$ to dulcamarine, and $C_{16}H_{26}O_6$ to dulcamaretin. (Flückiger, *Pharmacopgraphia*, 2d ed., p. 451.) (For account of *solanine*, see previous article.) Besides solanine, the stalks of *S. Dulcamara* contain, according to Pfaff, a peculiar principle to which he gave the name of *picroglycion*, indicative of the taste, at once bitter and sweet, which it is said to possess. This was obtained by Blitz, in the following manner: The aqueous extract was treated with alcohol, the tincture evaporated, the residue dissolved in water, the solution precipitated with lead subacetate, the excess of this salt decomposed by hydrogen sulphide, the liquor then evaporated to dryness, and the residue treated

with acetic ether, which yielded the principle in small isolated crystals by spontaneous evaporation. Frederick Davis (*Y. B. P.*, 1902) found the two alkaloids, *solanine* and *solanidine*, the glucoside *solanein*, and the bitter principle *dulcamarin*, in fresh specimens of the plant.

Dulcamara possesses feeble narcotic properties, with the power of increasing the secretions, particularly those of the kidneys and skin. George B. Wood observed, when the system was under its influence, a dark purplish color of the face and hands, and at the same time considerable languor of the circulation. In overdoses it produces nausea, vomiting, faintness, vertigo, and convulsive muscular movements. (*London Med. Gaz.*, 1850.)

Anaphrodisiac properties have been attributed to dulcamara, and it has also been employed with alleged benefit in chronic *rheumatism*. But its chief use has been in the treatment of scaly cutaneous eruptions, such as *lepra*, *psoriasis*, and *pityriasis*. A fluidextract is official in the N. F. (see Part III). Dulcamara may be given in *doses* of from thirty grains to a drachm (2–3.9 Gm.).

D. Freire has obtained from the fruit of *S. grandiflorum*, or wolf fruit, of Brazil, a toxic alkaloid, *grandiflorine*. (*C. R. A. S.*, cv.)

S. Jacquinii Willd. is used in India as a diaphoretic and expectorant.

S. Lycopersicum L. *Tomato Plant* (formerly termed the *Love Apple*).—The tomato is believed by many practitioners to be an injurious article of diet to gouty persons on account of the great acidity of the juice, an acidity which T. D. McElhenie has demonstrated to be due at least in part to citric, malic, and oxalic acids. (*A. J. P.*, 1872.) Solanine is said not to be present in the juice but has been found by George W. Kennedy (*P. J.*, 1873) in the herbaceous part of the plant. It probably also exists in the seeds. (*A. J. P.*, xxxiv.)

S. nigrum L. *Black*, or *Garden*, or *Common Nightshade. Duscle. Hound's Berry. Morelle.*—This is a simple leaved annual plant, growing widely in shaded and rich open ground throughout the United States. The leaves have been used in medicine in the treatment of *scrofulous dyscrasias*, and are said to produce diaphoresis when in overdose; also nausea, purging, and nervous disturbance. The poisonous properties commonly attributed to this plant are, however, to be doubted, since Dunal of Montpellier, states, as the result of numerous experiments, that the berries are not poisonous to man or the inferior animals; and the leaves are said to be consumed in large quantities in the Isles of France and Bourbon and in the Hawaiian Islands by the natives as food, having been previously boiled in water. In the latter case the active principle of the plant may have been extracted by decoction. Introduced by importers under the name of *jurubeba*, this plant was examined by Kobert and found to be inert. According to Peckoldt, however (*Ph. Rund.*, 1889), true jurubeba is *Solanum insidiosum* Mart., from which the results would have been more favorable. It is used in Brazil in *gonorrhea* and *syphilis*.

S. Pseudocapsicum L., or *Jerusalem* or *Winter Cherry*, a plant cultivated for greenhouse or house decoration when covered with its bright colored berries, yields a fruit whose resemblance to the common cherry is said to have led to its being eaten by children with fatal results.

S. rostratum Dunal. *Sand Bur. Buffalo Bur. Beaked Nightshade. Bull Nettle.*—This very prickly plant, which grows on the prairies from Nebraska to Mexico, and is noteworthy as having been the original food of the Colorado beetle or potato bug, has yielded to W. S. Amos an alkaloid. (*Notes on N. R.*, iv.)

Narcotic properties have been attributed to the leaves, stalks and unripe berries of *S. tuberosum* L., or common white potato, and the extract has been used in various diseases. Worsham, of Philadelphia, found the extract, in the quantity of nearly one hundred grains, to cause no sensible effect. (*Phila. Journ. of the Med. and Phys. Sciences*, vi, 22.)

A case is recorded of death in a girl of fourteen, from eating the unripe fruit of the potato. (*B. M. J.*, Sept. 3, 1859.) The prominent symptoms were partial stupor, speechlessness, jactitation, hurried breathing, lividness of the skin, cold sweats, very frequent and feeble pulse, and a constant spitting through the closed teeth of viscid frothy phlegm.

It is probable that the properties of the plant vary with the stage of growth, or with the place and circumstances of culture. C. Haaf found solanine in old potatoes which had begun to germinate, in the proportion of 0.16 in 500 parts, and in very young potatoes, deprived of their coating, precisely the same quantity. Fully ripe potatoes, which had not begun to sprout, gave a negative result. (*N. R. Pharm.*, 1864, p. 559.) Solanine has also been found in the germs of potatoes by Schmiedeberg. (*A. E. P. P.*, 1899, xxxvi, 361.)

Solidago. *Golden-rod. Verge d'Or*, Fr. *Goldruthe*, G.—There are very numerous species of this composite genus in the United States. Of these *S. odora* Ait., or the *Sweet Golden-rod*, was formerly official. *S. Virgaurea* L. [now *S. Raudii* (Porter) Britton], which occurs on dry or granitic soil in the northern United States and Europe, was formerly directed by the Dublin College. It is aromatic, astringent, in hot infusion diaphoretic, and is asserted to be diuretic. (*Rev. Gén. de Clin. et de Thérap.*, 1889.) For a study of the flowers of *S. bicolor* L., by Adam Conrath, see *A. J. P.*, 1873, 253. For an analysis of *S. rugosa* Mill., see *A. J. P.*, 1893, 122.

Soluble Mercury of Hahnemann. $NH_2(Hg_2)NO_3$.—This is prepared by adding, drop by drop, a diluted solution of ammonia to an equally diluted solution of mercurous nitrate, until the precipitate begins to be paler than at first. It is a black powder. When it has a gray color, the fact shows that too much ammonia has been employed in its precipitation. In this case $NH_2(Hg_2)NO_3$ yields $NH_2(Hg)NO_3 + Hg$. This preparation was included in the old French Codex. It has been used in *syphilitic* diseases.

Solurol. *Hyminic Acid. Nucleotinphosphoric Acid.* $C_{30}H_{46}N_4O_{15}.2P_2O_5$.—A yellow amorphous powder, easily soluble in water. It is used as an uric acid solvent in *gout*, *rheumatism* and similar affections. *Dose*, four to eight grains (0.25–0.5 Gm.).

Solution of Chlorinated Potassa. *Liquor Potassæ Chlorinatæ. Chlorure de Potasse*, Fr. *Chlorkalilösung*, G. *Javelle's Water. Eau de Javelle.*—This is prepared from potassium carbonate precisely as the solution of chlorinated soda is from sodium carbonate, and has an analogous composition. (See *Liquor Sodæ Chlorinatæ*, p. 655.) It is employed for taking out fruit stains, etc., from linen.

Solution of Dialyzed Iron. *Liquor Ferri Dialysatus. Liquor Ferri Oxychlorati*, P. G.—*Dialyzed solution of iron* was formerly recognized by the Br. Ph. It is made by treating a solution of ferric chloride with ammonia, whereby ferric hydroxide is precipitated, which by agitation is dissolved, placing the thick liquid in a dialyzer, and suspending this in water, which is to be constantly renewed so long as any traces of hydrochloric acid are found in it. The following process has been used in the United States: To one hundred parts of solution of ferric chloride, sp. gr. 1.26, thirty-five parts of ammonia water, sp. gr. 0.923, may be gradually added. The precipitate which almost immediately forms is redissolved, and the solution introduced into the dialyzer, which is then suspended upon the water, contained in a suitable vessel. When the water in the outer vessel ceases to produce a precipitate with silver nitrate, or to show an acid reaction, the preparation in the inner vessel is assayed by evaporating 10 mils to dryness on a water bath, to ascertain the amount of ferric oxychloride in solution; then the final solution is diluted so that it shall contain 10 per cent. of dry oxychloride.

Dialyzed iron is a colloidal solution of *ferric oxychloride* in water. The solution is of a transparent reddish-brown color, free from the usual astringent, styptic taste of iron preparations. It mixes in all proportions with distilled water, alcohol, syrup, and glycerin, but water containing any saline impurity is apt to cause precipitation. When gelatinization occurs, agitation with a small quantity of solution of ferric chloride will usually restore it to fluidity, care being observed not to add an excess. Contact with the alkalies should be avoided, even in minute quantity; indeed, it is best administered without addition of any kind, or simply diluted with distilled water.

The British Pharmacopœia formerly directed that its specific gravity should be 1.047, and "100 grains should afford a precipitate with a solution of ammonia which, washed, dried and ignited, weighs five grains." E. B. Shuttleworth (*Can. Pharm. Journ.*, Dec., 1877) recommends a solution which has the sp. gr. 1.040 and yielding 5 per cent. of residue when well dried on a water bath as the best for medicinal use. The specific gravity test can be relied upon, if the solution does not give a precipitate with silver nitrate or become of a blackish-blue color upon treatment with tannin, showing the absence of free ferric chloride. (See also *N. R.*, 1879, 46, for a new process by F. Schneider, from *S. W. P.*, 1878, 409.) There is good reason for believing that much of the so-called dialyzed iron formerly found in commerce was made by adding freshly precipitated ferric hydroxide to solution of ferric chloride until it ceased to be dissolved and then filtering the solution. (Scheffer, *A. J. P.*, March, 1878.) *Ferrum catalyticum*, or *catalytic iron*, used on the Continent, is probably made in this way.

Solution of dialyzed iron has been very highly praised as a ferruginous tonic free from astringency. It is capable of acting as an antidote to arsenic by virtue of the readiness with which it yields hydrated ferric oxide, but it is safer to depend upon the official antidote, ferric hydroxide with magnesium oxide (see p. 470). *Dose*, from one-half to one fluidrachm (1.3–3.75 mils).

Solution of Magnesium Bisulphite. *Liquor Magnesii Bisulphitis.*—George Archibald, having found that magnesium bisulphite is capable of arresting the butyric acid fermentation, proposed a solution of it as a remedy in *heartburn*. He prepared it by treating the magnesium carbonate with sulphurous acid, adding to an ounce of water sixteen grains of the sulphite thus formed, and passing sulphurous acid gas through the mixture until a clear solution is obtained. (*P. J.*, 3d series, ii, 502.)

Solutol.—An alkaline solution of sodium cresol in an excess of cresol. It is a transparent brownish liquid, miscible with water, and is used for disinfecting purposes.

Solveol.—A solution of sodium-cresylate in cresol. It is less caustic than solutol, is nearly odorless, of a neutral reaction, and miscible with water. It is used as surgical antiseptic, for dressings, and in spray apparatus.

Somatose.—This is an artificially digested meat albumin containing 51.6 per cent. of deutero- and 13.4 per cent. of hetero-albuminoses, 5 per cent. of peptone, 1 per cent. of moisture, and 5 per cent. of nutrient salts. A yellowish, odorless, and almost tasteless powder.

Iron Somatose is a similar preparation containing 2 per cent. of iron in combination.

Milk Somatose is a soluble nutrient prepared by the same digestive process from casein, containing 5 per cent. of tannin. It is a light yellowish powder, readily soluble in water.

Somnoform.—A proprietary anesthetic said to contain ethyl chloride 60 per cent., methyl chloride 35 per cent., ethyl bromide 5 per cent. Of late it has come into wide use in dental anesthesia, due to its thorough, yet fleeting action. While it has been stated that it possesses no unpleasant after-effects when properly administered, the numerous cases where stomachic disturbances have arisen after its use would lead one to doubt this statement. (For a study of its physiological action, see *B. M. J.*, 1903, 1.)

Sonatin.—This is a solution of benzoyl acid ($C_6H_5COC_6H_4COO$) in castor oil intended as a cheap and efficient substitute for the expensive balsam of Peru. It is claimed to be the equal of the latter in the treatment of many *skin diseases* where the balsam is indicated.

Sonchus. *Sonchus oleraceus* L. *Common Sow Thistle.* (Fam. *Compositæ.*)—A coarse weed, having runcinate-pinnatifid leaves clasping by a heart-shaped base and producing corymbs of pale yellow flowers in summer and autumn. This European plant is commonly found in waste places around dwellings in the United States. The brownish gum left after the evaporation of the juice of this plant is said to be a powerful hydragogue cathartic, in *doses* of from two to four grains (0.13–0.26 Gm.). Combined with aromatics or belladonna, it may be used instead of elaterium in *dropsy*. (*Med. Bull.*, July, 1888.) It has also been used as a so-called cure for the opium habit. (*Pac. Pharm.*, 1908, 113.)

Soot. *Fuligo Ligni.*—This well-known substance has a peculiar odor, and a bitter, empyreumatic, and disagreeable taste. Its composition varies according to the source and conditions of its formation. When obtained by the combustion of resinous materials it may contain oily distillation products soluble in ether; when obtained by the combustion of wood it may contain pyroligneous (acetic) acid and products peculiar to wood tar, such as creosote, guaiacol, and phenola. Of course mineral substances from the ash of the wood may also be present.

Soot was formerly official with the Edinburgh

College, and the Scotch physicians prescribed it as a tonic and antispasmodic. It has also been employed as an external remedy in skin diseases. (See *B. G. T.*, 1834; also 14th ed., *U. S. D.*) A few shovelfuls of it, thrown into privies or drains, effectually destroy their foul exhalations.

Sophora. *S. speciosa* Benth. *Coral Bean.*—From the poisonous seeds of this leguminous Texan tree, H. C. Wood obtained a volatile liquid alkaloid (*sophorine*) whose chloride is crystalline (see *A. J. P.*, 1878), and which, according to P. C. Plugge, is identical with cytisine. This same alkaloid probably exists in many species of the genus, as Parsons found a liquid alkaloid in *S. sericea* Nutt., *crazy-weed*, which grows in Colorado and Mexico (*Rep. Commissioner of Agricult.*, 1879, and *N. R.*, 1881, 67; see also Kalteyer and Neill, *A. J. P.*, 1866, 465), and Greshoff (*P. J.*, xxii). The latter found a poisonous alkaloid in the leaves of *S. tomentosa* L., the seeds and roots of which are used in Ceylon and Java as a remedy for *cholera*. Plugge, however (*A. Pharm.*, 1895), affirms that *matrine*, the alkaloid discovered by Nagai in *S. angustifolia*, is distinct from cytisine.

Sorbus. *Sorbus Aucuparia* L. (Now *Pyrus Aucuparia* (L.) Erhr.) *Mountain Ash. Rowan Tree. Sorbes*, Fr. *Eberesche, Vogelbeere*, G. (Fam. *Rosaceæ*.)—A small European tree extensively cultivated in the United States and becoming naturalized. Its fruit contains a peculiar kind of sugar called *sorbinose*, $C_6H_{12}O_6$, isomeric with levulose. It reduces Fehling's solution, but is not fermentable with yeast. Hofmann has also discovered two news acids, which he designates as *sorbic* and *parasorbic acids*, $C_6H_8O_2$. Sorbic acid forms colorless needle-like crystals fusing at 134.5° C. (274° F.), while parasorbic acid is a lactone-like body, which, on heating with concentrated acids or solid alkali, changes into sorbic acid. M. J. Boussingault has found in it a crystalline saccharine principle, *sorbitol*, isomeric with mannitol, melting, when anhydrous, at from 110° to 111° C. (230°–231.8° F.), when hydrated, at 102° C. (215.6° F.). Its formula is $C_6H_{14}O_6$. It does not undergo the vinous fermentation. (*P. J.*, 1872, 28.) The seeds of the fruit contain 22 per cent. of fixed oil. The fruit has been used in *scurvy*, and in infusion, as a remedy in *hemorrhoids* and *strangury*. All parts of the tree are astringent, and may be employed in tanning and dyeing black. *S. americana* Marsh. (now *Pyrus americana* (Marsh.) DC.), or *American Mountain Ash*, probably has similar virtues to the European species. Edwin Johanson found the fruit to yield from 4.92 to 6.6 per cent. of malic acid. (*Ph. Z. R.*, i, 1882.)

Sorghum.—A cane-like plant resembling Indian corn, from which it is distinguished by producing large heads of small grains. There are a number of varieties and these are usually distinguished as "saccharine" sorghums and "non-saccharine" sorghums. The former contain a sugary sap and are referred to *Andropogon arundinaceus* var. *saccharatus*. The latter are commonly known as *broom corn* or *Kaffir corn* and are varieties of *A. arundinaceus* var. *Durrha*. The saccharine sorghums are cultivated in the United States to some extent as a forage crop. They are not used in the manufacture of sugar, owing to the difficulty of effecting its crystallization. Broom corn has been cultivated in the United States since 1798 and is especially adapted to the manufacturer of brooms and brushes. In some of the semi-arid districts of the West it is reported that cattle have been poisoned from eating of the green sorghum, usually of a second growth. This is apparently due to the production of hydrocyanic acid in the leaves.

Sozal. *Aluminum Paraphenolsulphonate.* $(C_6H_4(OH)SO_3)6Al_2$.—This is obtained by dissolving aluminum hydrate in paraphenolsulphonic acid, or by double decomposition of aluminum sulphate and barium paraphenolsulphonate. It occurs in brownish crystalline grains having a weak phenol odor, but strongly astringent taste; easily soluble in water, glycerin, and alcohol, forming permanent solutions. It has been used as an antiseptic in place of iodoform. (*Ph. Ztg.*, 1892.)

Sozoiodolic Acid. *Sozoiodol. Diiodparaphenolsulphonic Acid, Crystalline.* $C_6H_2I_2(SO_3H)OH + 1\frac{1}{2}H_2O$.—This is a white glistening powder, odorless, of slightly acid taste, slightly soluble in cold water, more easily in hot water. It is decomposed on heating to 200° C. (392° F.), giving off violet vapors. It contains about 53 per cent. of iodine. It can be recognized by heating, or by adding sulphuric acid to it in hot solution, when iodine separates. Ferric chloride imparts a dark violet color to the aqueous solution; silver nitrate throws down a white precipitate of silver soziodol completely soluble in diluted nitric or sulphuric acid. For an outline of the process of manufacture, see *Squibb's Ephem.*, Feb., 1893. Soziodol is used as a local remedy, resembling somewhat iodoform in its range of usefulness. According to Langaard, 2 per cent. is sufficient to kill bacteria of pus; for wounds, a 10 per cent. mixture with powdered talc is advocated. Lassar praises it in *eczema, herpes tonsurans, impetigo*, etc.; it has also been much used in *otitis* and *rhinitis*. Langaard has found that fifteen-grain doses have no appreciable effect upon rabbits, and Bufalini gave twenty-two grains a day in *phthisis* without unpleasant effect. The soziodolates have also been called by the proprietary name of *Ronozol salts*. The following salts have been used:

Potassium sozoiodol, sparingly soluble; a desiccant indicated in *eczema*. It is usually employed with talc in the proportion of 1: 5 or 1: 6. *Zinc sozoiodol*, a local irritant in solutions of from 1: 20 to 1: 50; a caustic, in a solution of 1: 5. *Mercury sozoiodol*, a caustic, even in a solution of 1: 10. Miller affirms that its solution of 2½ per cent. kills the acarus of *scabies* in twenty-four minutes. It has been used as an antisyphilitic in *doses* of one grain (0.065 Gm.).

Schwarz recommends pills, each containing one-third of a grain of sozoiodol mercury and one-fifteenth of a grain of powdered opium. (*Th. M.*, 1908, 299.)

Sodium Sozoiodolate (*sodium soziodol*) occurs as colorless, inodorous, crystalline needles, soluble in about fifteen parts of water, also soluble in alcohol or glycerin. The finely powdered substance mixed with equal parts of sulphur is employed by insufflation in treating *diphtheria, laryngitis, nasal tuberculosis*, etc. It is also used in a 2 to 5 per cent. solution as an antiseptic douche or wash in *gonorrhea*.

Sozolic Acid. *Acidum Sozolicum. Orthophenolsulphonic Acid.* $C_6H_4(SO_3H)OH$.—Ortho and paraphenolsulphonic acids are both formed when phenol is dissolved in concentrated sulphuric acid; at medium temperatures the former is far more abundant, but it readily passes into the para compound on the application of heat. Sozolic acid has a very faint odor of phenol. It is readily soluble in water, alcohol, and glycerin, and is used so diluted as to contain from 3 to 10 per

cent. of the active principle. The orthophenolsulphonic acid in 33⅓ per cent. solution has received the trade name of *aseptol*. The ortho acid changes on heating into the isomeric paraphenolsulphonic acid, and this change takes place even in the aqueous solution of the former, a fact which should be remembered in the preparation of aseptol solutions.

E. Riegler (*W. M. Bl.*, xviii, 1895) proposes aseptol as a test for albumin in urine. One part in 20,000 causes coagulation; the precipitate with albumin does not disappear with heat. The solutions of albuminose and peptones are also precipitated, but the precipitates of these disappear with heat. The solution of aseptol undergoes decomposition when exposed to light.

Schiff and Beilstein asserted that phenolsulphonic acid acts like tannic and gallic acids, precipitating albumen and alkaloids, and being capable of replacing gallic acid in the making of leather and in pharmacy. There is, however, no sufficient reason for believing that the substance can be used in medicine in the place of the vegetable acids named. It has also been asserted that phenolsulphonic acid is a powerful antiseptic, but in a careful series of comparative experiments, F. A. Tucker (*Notes on New Remedies*, 1892) found that it had not more than one-third the antiseptic power of phenol.

Spartium. *Spartium junceum* L. *Spanish Broom.* (Fam. *Leguminosæ.*)—A small shrub, indigenous in the south of Europe, and cultivated in our gardens as an ornamental plant. The flowers are large, yellow, and of an agreeable odor. Spanish broom, in its medicinal properties closely resembles *Scoparius*, but appears to be from five to six times more active, 6 Gm. of the dried plant, given in infusion, having produced very violent poisoning; serious results have been produced by the substitution of the Spanish for the true broom. The dried flowers are readily differentiated, those of the *true broom* having a small, bell-shaped calyx with two unequal lobes, the upper of which is bidentate, the lower minutely tridentate, and the style always rolled, while in *Spartium junceum* the calyx is deeply cleft to the base on one side only, and the style is deeply rolled.

The symptoms produced by overdoses are vomiting and purging, with renal irritation. The seeds have been used to a considerable extent in *dropsy* in *doses* of from ten to fifteen grains (0.65–1.0 Gm.) three times a day in the form of tincture.

Sphæranthus. *Sphæranthus indicus* L. (Fam. *Compositæ.*)—An herbaceous plant having winged stems and widely distributed in Africa, Asia and Australia. It is used as a general tonic, deobstruent, alterative, and aphrodisiac, under the names of *Mundi Gorakhmundi*, *Murmuria*, and *Kottakkarandai*. Dymock has found it in a deep cherry-colored essential oil.

Spider Poisons.—The popular belief that certain spiders have the power of poisoning small animals, and even man, has received confirmation, and an active principle, *arachnolysin*, has been separated by Sachs and found to have a powerful hemolytic action upon the blood of rabbits and cats but not to affect dogs and guinea-pigs. (See Kobert, *Giftspinnen*, 1901; *S. Jb.*, Bd. 274, 178.)

Spilanthes. *Spilanthes Acmella* Murr. (*S. oleracea* L.) *Para Cress. Cresson de Para*, Fr. *Parakresse*, G. (Fam. *Compositæ.*)—A plant of India, used as a masticatory for *toothache;* when chewed it produces a copious salivation. (*A. J. P.*, xliv, 323.)

Spiracin. *Methyl-carboxyl-salicylic Acid.*—It forms a white crystalline powder, insoluble in water. It is used for the same purposes as the salicylates in *doses* of ten to fifteen grains (0.6–1 Gm.).

Spiræa.—Many if not all of the species of this genus contain a colorless volatile oil, very similar to the oil of gaultheria, but composed mainly of salicylic aldehyde, with only smaller amounts of methyl salicylate. The species which have been submitted to actual analysis are the *Spiræa Ulmaria* L. (*Filipendula Ulmaria* (L.) Maxim.), commonly known as *Queen of the Meadow*, or *Meadow-sweet*—a European plant which has been introduced into this country; also the European species *S. lobata* Jacq. and the species *S. Filipendula* L. (*Filipendula vulgaris* Moench.), which grows in Southern Europe and Northern Africa. A yellow, crystalline powder of a bitter taste, insoluble in water, slightly so in alcohol, readily soluble in ether, and having an acid reaction. *Spiræic acid* (now recognized as salicylic acid) (*J. Pr. Chem.*, xix) was separated from the flowers of *S. Ulmaria* by Löwig and Weidmann, and has been found by Rochebrune in the flowers of *S. Filipendula* L.

The roots of probably most of the species contain tannic acid, gallic acid, and when fresh some of the volatile oils. (*A. J. P.*, 1887.) The root of *Spiræa tomentosa* L. (*Hardhack, Steeplebush*, or *Whitecap*), was formerly recognized in the U. S. Pharmacopœia. It is an indigenous shrub growing in low grounds from New Brunswick and Nova Scotia to the mountains of Georgia and westward. The stems and lower surfaces of the ovate-lanceolate, serrate leaves are whitish and tomentose. The rose-colored flowers are disposed in terminal, compound, crowded spikes or racemes.

The flowers of *Spiræa* possess to a very feeble extent the medicinal virtues of salicylic acid, and have been used as diuretic and tonic in the form of decoction. The roots are astringent, and have been used in the treatment of *diarrhea* in *doses* of from five to twenty grains (0.32–1.3 Gm.) of the aqueous extract repeated *pro re nata*.

Spiroform. *Vesipyrin. Acetyl Salol. Acetylphenyl-o-oxybenzoic Acid. Acetyl Salicylic Phenyl Ester.* $C_6H_4(OCH_3CO)COOC_6H_5$.—A tasteless, odorless powder, insoluble in water, readily decomposed by alkalies. This substance acts in the body much like phenyl salicylate; it passes through the stomach unchanged, but is broken up in the intestines, liberating salicylic acid. It was originally introduced as a urinary antiseptic, but has also been employed as an antirheumatic and analgesic. The *dose* is from eight to fifteen grains (0.5–1.0 Gm.).

Spirosal. *N. N. R.* 1917. *Mono-glycol Salicylate.* $C_6H_4OH.CO.O(CH_2.CH_2.OH)$.—It occurs as an almost colorless and odorless liquid, freely miscible with alcohol, and with eight parts of olive oil. It has been brought forward as a means of administering salicylic acid endermically. According to Schoenheim (*Med. Klin.*, 1907) it is more rapidly absorbed through the skin than the other preparations of salicylic acid intended for percutaneous absorption, and a number of clinicians have reported favorably upon its application in various forms of *rheumatism*. It has also been suggested for the treatment of *furunculosis* of the external auditory canal. It is applied either un-

diluted, or mixed with equal parts of alcohol, about a drachm at a *dose*, well rubbed into the skin, and then covered with impermeable dressing.

Sponge. *Spongia. Spongia officinalis. Eponge*, Fr. *Schwamm. Badeschwamm*, G.—The sponge is "a flexible, fixed, torpid, polymorphous animal, composed either of reticular fibers or masses of small spires interwoven together, and clothed with a gelatinous flesh, full of small mouths on its surface, by which it absorbs and ejects water." Until recently sponges were classified as colonial *Protozoa*, the lowest group of animals, but they are now brought under a separate phylum known as *Porifera* (or *Spongiaria*) a name applied to them because of their abundance of water pores. The latter are of two kinds, both opening into the digestive canals and ramifying passages of the sponge. Some of these are large, but most of them are small, being in the nature of inhalent pores or inlets for admitting the water. The current through these pores is a constant one which is induced by countless flagella which occur in definite enlargements on the canals and known as ciliated chambers. This current contains the minute organisms which are carried to the digestive cavities and upon which the animal feeds. Through these canals oxygen is distributed, the waste matters eliminated and fertilization of the eggs is effected. Sponges inhabit the bottom of the sea, where they are fixed to rocks or other solid bodies, and are most abundant within the tropics. They are collected chiefly in the Mediterranean and Red Seas, the West Indies and the coast of Florida and Central America. In the Grecian Archipelago, Crete, Cyprus, on the coast of Asia Minor, Syria, Barbary and the Bahama Islands, sponge fisheries constitute a very important industry. Formerly most of the sponges used in the United States were brought from the Mediterranean waters, but since 1852 the Bahamas and the coast of Florida have furnished much of the commercial supply. When collected they are enveloped in a gelatinous coating, which forms part of the animal. For details of fishery and preparation, see *P. J.*, xx. Large quantities of the coarser kinds are imported from the Bahamas, but the finest and most esteemed are brought from the Mediterranean, especially from the coast of Syria. Recently the cultivation of sponges has been undertaken on an extensive scale. Small fragments are cut under water from the live sponge, and fixed upon a sandy bottom by means of skewers. In three years they will have grown sufficiently to be marketable.

Sponge, as found in commerce, is in yellowish-brown masses of various shapes and sizes, light, porous, elastic, and composed of fine, flexible, tenacious fibers, interwoven in the form of cells and meshes. It usually contains numerous minute fragments of coral or stone, or small shells, from which it must be freed before it can be used for ordinary purposes. Sponge is prepared by macerating it for several days in cold water, beating it in order to break up the concretions which it contains, and dissolving what cannot thus be separated of the calcareous matter by hydrochloric acid diluted with thirty parts of water. By this process it is rendered perfectly soft, and fit for surgical use. It may be bleached by steeping it in water impregnated with sulphurous acid, or by exposure in a moist state to the action of chlorine. It is stated that sponges which have been soaked in pus and infectious matters will recover their primitive condition by soaking in a 4 per cent. solution of potassium permanganate, then in a 25 per cent. solution of official sulphurous acid, and finally thorough washing in an abundance of water. (*A. J. P.*, xliv, 355.) When intended for surgical purposes, the softest, finest, and most elastic sponges should be selected; for forming *burnt sponge* the coarser will answer equally well. According to Hatchett, the chemical constituents of sponge are gelatin, coagulated albumin, common salt, and calcium carbonate. Magnesia, silica, iron, sulphur, and phosphorus have been detected in it, as also iodine and bromine, combined with sodium and potassium. From the experiments of Croockewit, it would appear that sponge is closely analogous to, if not identical with, the *fibroïn* and *sericin* of silk, differing from it only in containing iodine, sulphur, and phosphorus. (*Ann. Ch. Ph.*, xlviii, 43.) Schlossberger, however, has shown that it is distinct, in its very slight solubility in ammoniacal solution of copper hydroxide and in its yielding leucine and glycocoll when treated with diluted sulphuric acid, while sericin yields under similar treatment tyrosine and serin. He names the principle *spongin*.

Sponges are used for mechanical purposes only. *Sponge tent* is employed for dilating sinuses. This is prepared by dipping sponge into melted wax, compressing it between two flat surfaces till the wax hardens, and then cutting it into pieces of a proper form and size. By the heat of the body the wax becomes soft, and the sponge, expanding by the imbibition of moisture, gradually dilates the wound or sinus in which it may be placed. When a conical sponge tent of uniform caliber is required, as for dilating the uterine cavity, a better plan is to cut the sponge into a conical shape while fresh and compress when moist, by winding it carefully with a fine tightly drawn cord, removing the cord when perfectly dry, and dipping the tent into melted wax, so as to get a thick coating. For other modes of preparing sponge tent, as well as of saturating the sponge at the same time with substances calculated to make a remedial impression, as phenol, alum, lead acetate, etc., see *A. J. P.*, 1868, 410; 1869, 446.

Spongia Usta, *Burnt Sponge*, was formerly official (*Spongia Usta*, U. S. 1850), but is no longer used in medicine. For method of preparation, analysis, and therapeutic properties, see 16th edition, *U. S. D.*

Statice. *Statice Limonium* (L.) Gray. [Now *Limonium carolinianum* (Walt.) Britt.] *Marsh Rosemary. Ink Root. Sea Lavender. Romarin des Marais, Lavande triste*, Fr. *Strandnelke*, G. (Fam. *Plumbaginaceæ.*)—It is an indigenous maritime plant with a perennial, very astringent, root, sending up annually tufts of leaves, which are obovate or cuneiform, entire, obtuse mucronate, smooth, and on long foot-stalks.

Marsh rosemary grows in the salt marshes along the sea coast from Labrador to Texas, and flowers from July to September. The root, which was formerly in the Secondary List of the U. S. Pharmacopœia, is large, spindle-shaped, or branched, fleshy, compact, rough, and of a purplish-brown color. It is bitter and extremely astringent, but odorless. It contains tannic acid (12.4 per cent.), volatile oil, resin, and other substances. (*A. J. P.*, xiv, 116.) *Statice* is powerfully astringent, and in some parts of the United States, particularly in New England, is much employed, especially as a local application, in de-

coction, to aphthous and ulcerative affections of the mouth and fauces.

In Brazil and Buenos Ayres the roots of *S. brasiliensis* Boiss. are employed under the name of *Buaycura* or *Guaycura*. (*P. J.*, 1878, ix, 466.) For a description of the physical and chemical characteristics of the root, see *P. J.*, vol. xv, 86. In Russia and Spain the very large roots of *S. latifolia* Sm. are used for tanning, and in Morocco the roots of *S. mucronata* L. are stated to be employed, under the name of *safrifa*, as a nervine.

Steresol.—An antiseptic varnish made by dissolving purified shellac 270 parts, benzoin 10 parts, balsam of Tolu 10 parts, phenol in crystals 100 parts, oil of cinnamon 6 parts, saccharin 6 parts, in sufficient alcohol to make 1000 parts. It permits of asepsis of mucous surfaces, and is adapted for use where it is impossible to apply bandages.

Sterisol. *Steriosol.*—According to Aufrecht, this liquid contains formaldehyde, sodium chloride, potassium phosphate, sugar of milk, and water. It is used as an antiseptic.

Sticta. *Lungmoss. Lungwort.*—The lichen *Sticta pulmonaceæ*, a native of Europe, used largely by the natives in the treatment of *pulmonary complaints*. It owes its activity chiefly to *stictic acid*, which is bitter and possesses a powerful astringent action.

Stipa.—According to Gillespie (*B. M. J.*, Oct., 1898), a number of species of this genus of grasses are actively poisonous, and have caused death in horses and other domestic animals. Of such character especially are *Stipa viridula* Trin., *Stipa inebrians* Hance, and *Stipa sibirica* Lam., of the Russian steppes. A few experiments made with *Stipa viridula* Trin., a plant growing in the prairies and meadows from western Minnesota to the Dakotas and southernward, indicated that it acts powerfully upon the brain and spinal cord.

Stipa Vaseyi Scribner.—According to Vernon Bailey this grass, which grows on the mountains of California, is a very active narcotic, producing in animals, which graze upon it, sleep lasting for a week or longer. (See Farwell, *Merck's Rep.*, 1911, p. 271.)

Stovaine. *N. N. R.* 1917. *Amylene AB. Hydrochloride.* (*Hydrochloride of Benzoyl-dimethylamino-propanol*, $CH_3CH_2C(C_6H_5COO)(CH_3)CH_2N(CH_3)_2HCl$.—It is closely related to alypin (see page 1239). It crystallizes in small, brilliant scales, melting at 175° C. (347° F.), and is very soluble in water. It shows most of the reactions of cocaine, which is also a benzoyl derivative.

This substance which has been advertised by methods approaching that employed by the mountebank has been used as a local anesthetic especially for the production of the so-called *spinal anesthesia* by a very large number of surgeons. In the experiments of LeBrocq (*B. M. J.*, March 27, 1909) it was found that if the toxicity of cocaine represented 1 that of stovaine would be 0.625 and that of eucaine 0.414; in other words it stands midway between cocaine and eucaine in danger. He also found that it was locally irritant, its injection being followed by intense hyperemia and even local sloughing. As confirmatory of this local irritant effect are the changes which have been found in the spinal cord from its lumbar injection. Pauterier and Simon (*Bull. Hop. Par.*, 1907) report a case of meningitis following spinal anesthesia with the agent and Spiller and Leopold (*J. A. M. A.*, 1910, liv, p. 1840) caused intense degeneration of the posterior columns of the cord by repeated injections in the lower animals. In 1907 Chaput (*Press. Med.*, 1907) collected statistics of 3174 spinal anesthesias with stovaine with six deaths, mortality of about one in 530. In the same year, however, Torrance collected 5532 cases with but 3 deaths. It is evident that the mortality of spinal anesthesia from stovaine is higher than that of general anesthesia with ether or chloroform. Schwarz (*Cb. C.*, 1907) reported signs of renal irritation in 78 per cent. of cases anesthetized by this method, but Hosemann (*Cb. C.*, 1908, xxxv, 60), in a series of sixty cases, noted mild irritation of the kidney in only ten cases, in none of which was there permanent injury.

As a local anesthetic stovaine has the advantage over cocaine of being somewhat less toxic, of not dilating the pupil or causing vascular constriction, and of withstanding boiling temperatures. Weight for weight, it is probably the most powerful anesthetic of all the cocaine substitutes, according to LeBrocq, surpassing even cocaine itself. For local anesthesia it is generally employed in a 1 per cent. solution of which sixteen to fifty minims (1–3 mils) may be injected, according to the size of the area it is desired to render insensible. For spinal anesthesia it is recommended to be used in strengths of from 3 to 10 per cent., injecting a quantity of this solution equivalent to from 0.032 to 0.065 Gm. of the drug.

Strontium Acetate. $Sr(C_2H_3O_2)_2 + \frac{1}{2}H_2O$.—This is a white crystalline powder, soluble in water. It is said to possess anthelmintic properties. It is given in *doses* of from ten to thirty grains (0.65–2.0 Gm.) twice a day.

Strontium Arsenite. $Sr(AsO_2)_2 + 4H_2O$.—A white powder soluble in water. It possesses the therapeutic virtues of arsenic, but has no advantages over the official preparation. The *dose* is from one-thirtieth to one-fifteenth of a grain (0.002–0.004 Gm.).

Strontium Carbonate. *N. F. IV. Strontii Carbonas.*

"It contains, when dried to constant weight at 100° C., not less than 99 per cent. of $SrCO_3$ (147.62)." *N. F.*

"Strontium Carbonate occurs as a white powder, odorless and tasteless. It is insoluble in water; dissolved with effervescence by diluted hydrochloric, nitric, or acetic acid; the addition of diluted sulphuric acid to these solutions produces a white precipitate. One Gm. of the salt yields a clear, or not more than slightly turbid, solution, with 10 mils of diluted hydrochloric acid (*sulphate*). A solution of 0.1 Gm. of the salt in 10 mils of distilled water made with the aid of nitric acid does not immediately become more than slightly opalescent on adding silver nitrate T.S. (*chloride*). Dissolve 1 Gm. of Strontium Carbonate in distilled water with the aid of a slight excess of acetic acid, dilute to 100 mils and to 10 mils of this solution add 5 drops of potassium dichromate T.S.; no turbidity develops within five minutes (*barium*). Shake 2 Gm. of the salt with 25 mils of distilled water, filter, evaporate the filtrate and dry the residue at 100° C.; it weighs not more than 0.01 Gm. (*soluble substances*). A solution of the salt in a slight excess of diluted hydrochloric acid does not respond to the Test for heavy metals.

"*Assay.*—Dissolve about 1.5 Gm. of Strontium Carbonate, dried to constant weight at 100° C. and accurately weighed, in 30 mils of normal

hydrochloric acid V.S. and titrate the excess of acid with normal sodium hydroxide V.S., using methyl orange T.S. as indicator. It shows in the dried salt not less than 99 per cent. of $SrCO_3$.

"Each mil of normal hydrochloric acid V.S. consumed is equivalent to 0.07381 Gm. of $SrCO_3$. Each gramme of Strontium Carbonate requires not less than 13.4 mils of normal hydrochloric acid V.S." *N. F.*

It is not used medicinally, but was introduced into the N. F. for the preparation of the compound elixir of formates.

Strontium Lactate. *Strontii Lactas. U. S.* 1890. $Sr(C_3H_5O_3)_2.3H_2O = 319.76$.—This salt may be prepared by the process of Thumann. (See *U. S. D.*, 19th ed., p. 1661.) *Strontium lactate* is "a white, granular powder, or crystalline nodules, odorless, and having a slightly bitter, saline taste; permanent in the air. Soluble in about 4 parts of water at 15° C. (59° F.), and in less than 0.5 part of boiling water. The solution saturated at a boiling heat remains liquid for many hours, even after being cooled to 0° C. (32° F.). Soluble in alcohol. When heated to 110° C. (230° F.), the salt loses its water (16.9 per cent.). At a higher temperature it first fuses, then is decomposed, giving off inflammable vapors, and leaves a residue of strontium carbonate and carbon, which, on the addition of hydrochloric acid, effervesces and communicates an intense, red color to a nonluminous flame. The aqueous solution (1 in 20) is slightly acid to litmus paper." *U. S.*, 1890. It gives the characteristic reactions of the soluble salts of strontium and the lactates. The absence of barium may be shown by potassium dichromate T.S., which should produce no turbidity. For further tests of purity, see *U. S. D.*, 19th ed., p. 1662.

Uses.—Strontium lactate was originally brought forward by J. V. Laborde, who found it to have a distinct diuretic action. His researches led to clinical studies of the drug by German Sée, Paul, Dujardin-Beaumetz, and others. It is asserted that strontium lactate is an extremely successful remedy in the treatment of *nephritis* and chronic *albuminuria*, the urine being increased, the albumin lessened or entirely removed, and the genéral nutrition improved. The experiments, however, of Wood and Arnold (*Phila. Monthly Med. Journ.*, April, 1899) have shown that only infinitesimal amounts of the drug are absorbed from the intestines. Upon the intestinal canal the lactate is asserted to exert a very favorable influence. Strontium lactate has also been tried with alleged good results in the treatment of *rheumatism* and *gout*, it being affirmed that it increases the nitrogenous elimination and causes disappearance of the urates. *Dose*, from ten to thirty grains (0.65–2.0 Gm.) three times a day in solution.

Strontium Phosphate. $Sr_3(PO_4)_2$.—A white, tasteless powder, soluble with decomposition in acids. Nutritive and tonic. It is used in the treatment of *phthisis* and other wasting diseases, as a tissue builder, asserted to be superior to calcium phosphate. (Labordé.) *Dose*, ten to thirty grains (0.6–2.0 Gm.).

Strontium Sulphide. *Strontii Sulphidum.* SrS.—This substance has been used to some extent as a depilatory, in accordance with the following method: A powder of 2 parts strontium sulphide, 3 parts of zinc oxide, and 3 parts of powdered starch, kept dry until used, is formed into a paste with warm water and allowed to remain upon the surface from which the hair is to be removed from one to five minutes, being taken off so soon as pronounced pain or any evidences of caustic action are perceptible. The surface should then be gently but firmly scraped with a blunt edge like that of a paper knife, then washed well with warm water, and treated with an emollient.

Strychnine Arsenate. *Strychninæ Arsenas.*—*Strychnine arsenate* has been introduced as a means of obtaining the effects of its constituents. It is especially praised by Coriveaud (*K. T. W.*, 1909) in the treatment of *bronchial asthma* and other pectoral complaints. The *dose* is one sixty-fourth of a grain, increased to one-fifteenth (0.001–0.004 Gm.). (*W. M. Bl.*, Sept., 1886.)

Strychnine Glycerophosphate. *N. F. IV. Strychninæ Glycerophosphas. Strychnine Glycerinophosphate.*—This strychnine salt was introduced into the N. F. IV to be used in making the compound elixir of glycerophosphates.

"The glycerophosphate $[(C_{21}H_{22}O_2N_2)_2PO_4H_2(C_3H_7O_2) + 6H_2O = 948.60]$ of the alkaloid strychnine. Preserve it in well-stoppered bottles." *N. F.*

"Strychnine Glycerophosphate occurs in white, rhombic crystals or as a white powder; odorless; having at first a faint, sweet taste, afterward becoming intensely bitter. One gramme dissolves in about 350 mils of water, the solution being neutral or slightly alkaline to litmus; also in about 310 mils of alcohol; slightly soluble in chloroform, and very slightly soluble in ether. On incinerating 0.2 Gm. of the salt it yields no weighable residue. The addition of sulphuric acid to the salt produces no color, or at most only a slight yellowish coloration, but on subsequently adding a fragment of potassium dichromate a deep blue color is obtained, which changes to deep violet, then to purplish-red, cherry-red and finally to orange or yellow. Add ammonia water in slight excess to a saturated aqueous solution of the salt; a white precipitate is formed which is readily soluble in chloroform. A saturated aqueous solution of the salt, acidulated with diluted nitric acid, is not rendered more than faintly turbid on the addition of silver nitrate T.S. (*chloride*). A saturated aqueous solution of the salt, acidulated with hydrochloric acid, shows not more than a slight turbidity on the addition of barium chloride T.S. (*sulphate*). Add a slight excess of ammonia water to an aqueous solution of the salt and filter the mixture; the filtrate shows not more than a slight turbidity with magnesia mixture T.S. (*phosphate*)." *N. F.*

It has no advantages medicinally over other strychnine salts.

Strychnine Valerate. *N. F. IV. Strychninæ Valeras.*—This salt was introduced into the National Formulary to be used in elixir of strychnine valerate, a preparation of doubtful utility since the amount of valeric acid present can have no useful therapeutic action in a teaspoonful *dose* which contains only one-hundredth of a grain of the strychnine valerate and the latter contains only two-thirds of its weight of strychnine.

"The valerate $[C_{21}H_{22}O_2N_2.HC_5H_9O_2 = 436.28]$ of the alkaloid strychnine. Preserve it in well-stoppered, amber-colored vials." *N. F.*

"Strychnine Valerate occurs as a white crystalline powder, having an odor of valeric acid and an intensely bitter taste. It is sparingly soluble in water, becoming less soluble on keeping, through the loss of valeric acid; soluble in alcohol or chloroform; slightly soluble in ether. Its saturated

aqueous solution is neutral or slightly alkaline to litmus. Dissolve about 0.05 Gm. of Strychnine Valerate in 2 mils of sulphuric acid; no more than a faint yellowish color appears, but on adding a fragment of potassium dichromate a deep violet color is produced which changes to orange or yellow. When sulphuric acid is added to the salt, the odor of valeric acid is evolved. Incinerate 1 Gm. of Strychnine Valerate; the ash does not exceed 0.1 per cent. Ten mil portions of an aqueous solution of the salt (1 in 100) are not affected at once by barium chloride T.S. when acidulated with hydrochloric acid (*sulphate*) nor by silver nitrate T.S. when acidulated with nitric acid (*chloride*). About 0.02 Gm. of the salt, moistened with nitric acid, may be colored yellow, but not red or reddish (*brucine*)." *N. F.*

The average *dose* of strychnine valerate is given as one-fortieth of a grain (0.0015 Gm.).

Strychnos Potatorum L. *Chilbinj. Clearing Nuts. Indian Gum Nuts.* (Fam. *Loganiaceæ.*)—The nuts of this species of *Strychnos* are very largely used in some parts of India for clearing muddy water, and are stated to have found their way into American commerce. (*A. J. P.*, 1871.) The fruit is also employed by the native practitioners of Hindostan, under the name of *nirmali*, as an emetic and in *dysentery*. They do not contain strychnine. In clearing water, one of the dried nuts is rubbed hard for a short time around the inside of the earthen water pot; on settling, the water is left pure and tasteless. The seeds contain a large quantity of an albuminous principle, upon which their virtues probably depend. The tree, which grows to a very large size, produces a shining, black, one-seeded berry (that of the nux vomica being many-seeded). The seeds are described (*P. J.*, 1871, 44) as broadly lenticular, about half an inch in diameter and a quarter of an inch in thickness, of a dirty whitish-gray color, and covered with a thick coating of delicate appressed hairs. These are so small that the seed to the naked eye looks mealy. Under the microscope the hairs are seen to be agglutinated in groups of from three to six, and to consist each of a single pointed cylindrical cell.

Stylophorum. *Stylophorum diphyllum* (Michx.) Nuttall. (Fam. *Papaveraceæ.*)—This plant, commonly known as "*Celandine Poppy*," is found in damp woods from western Pennsylvania to Wisconsin and Tennessee. In its foliage and flowers it resembles *Chelidonium majus*. According to E. Schmidt, the root contains *chelidonine*, with a second alkaloid closely related to, if not identical with, *chelerythrine*. (*A. J. P.*, 1888.)

Styptic Collodion. *N. F. IV* (*U. S. P. VIII*). *Collodium Hæmostaticum, Styptic Colloid, Xylostyptic Ether. Collodion styptique, Collodion au tannin*, Fr.; *Tannin-Kollodium*, G. (See under *Collodium Stypticum*, Part III.)—When applied on wounded or abraded surfaces, it soon loses the ether and alcohol, and a firm coating is left, in which, besides the tannin and colloidal substances, are the coagulated blood and secretions from the surface, forming a covering for the part by which the air is excluded. The liquid is applied with a camel's hair brush, or by means of cotton saturated with it, to the edges of the wounds closed by stitches, to ulcerated surfaces, and bleeding parts. If it be desired to make a special impression on the diseased surface, phenol, creosote, iodine, morphine, etc., may be incorporated with the styptic fluid.

Styptic Colloid (Carbolized).—In this preparation advantage is taken of the antiseptic and styptic properties of phenol, and a very effective hæmostatic results. It is made by adding ten per cent. of phenol to styptic collodion.

Stylosanthes. *Stylosanthes biflora* (L.) B. S. P. (Fam. *Leguminosæ.*)—This low, branching perennial has wiry stems, 3-foliate leaves and small yellow flowers. It is found in the pine barrens of the Eastern and Central United States and it is asserted that it possesses the power of relieving abdominal uterine pains during the latter months of gestation, and is also a uterine tonic during parturition. *Dose*, of the fluidextract, from ten to twenty minims (0.6–1.3 mils) three times a day.

Styrone. *Cinnamic Alcohol. Styryl Alcohol.* $C_6H_5.CH : CH.CH_2.OH$.—A *beta-phenyl-allyl alcohol* appearing either as an aromatic oily fluid, boiling at 250° C. (482° F.), or a crystalline solid, forming white needles soluble in alcohol and fusing at 25° to 30° C. (77°–86° F.). The fluid is used in *otitis media* and the crystals as a deodorant and antiseptic either in the dry form or in a glycerin solution.

Subcutin.—This compound of paraphenolsulphonic acid with paramido-benzoic acid has been brought forward by Ritsert as non-toxic, distinctly germicidal, and locally anesthetic. It is a white, crystalline powder, soluble to the extent of 1 per cent. in cold water, and two and one-half per cent. in tepid water. For hypodermic use to this solution is added about 1 per cent. of ordinary salt. It is stated that it is especially adapted to the production of infiltration anesthesia.

Sublamine. *Hydrargyri Sulphas Æthylenediaminata. N. N. R.* 1917. $HgSO_4.2C_2H_4(NH_2) + 2H_2O$.—This is a white powder, soluble in water, composed of one molecule of mercuric sulphate and two molecules of ethylenediamine, and contains about 43 per cent. of mercury. It was originally brought forward as a non-irritant germicide of exceptional penetrative power, and especially useful for the purpose of disinfecting the hands and skin; used in solution varying from 1 to 1000 up to 1 to 200. It has also been highly commended in 1 to 300 for sterilizing suture silk by boiling.

Sublamine has also been employed to some extent for the hypodermic administration of mercury; it is affirmed by Schuftan, when given hypodermically, to be more active than corrosive sublimate, probably because it does not coagulate albumin. It is incompatible with sodium chloride and should not be exposed to the air.

Sublimo-Phenol. *Phenolated Mercuric Chloride. Chloro-phenolate of Mercury.*—Colorless crystals produced by precipitation when solutions of mercuric chloride and potassium phenolate are mixed. It is easily soluble in fused phenol or boiling aqueous or alcoholic solutions of phenol. It is used in antiseptic surgery.

Succinic Acid. *Acidum Succinicum. Sal Succini Volatile. Acide succinique*, Fr. *Bernsteinsäure*, G. $H_2C_4H_4O_4$.—This acid is obtained by distilling amber. The product is an aqueous solution of *succinic acid*, associated with empyreumatic oil. (See *Amber* and *Oil of Amber*, page 1239.) By filtering the liquor the solution of the impure acid passes through, while the oil is absorbed by the paper. The acid may be purified by boiling the solution with nitric acid, diluted with twice its bulk of water, and then evaporating to crystallize: should the crystals not be colorless, the treatment with nitric acid must be repeated until they are so. Succinic acid is made artificially by the action of nitric acid on the fatty acids, and

may be produced in a great many ways from various substances. Thus, it is invariably formed in small amount in the alcoholic fermentation of sugar. Desaignes obtained it more advantageously from calcium malate subjected to fermentation excited by casein. The malate was converted into calcium succinate, which was then decomposed by sulphuric acid, so as to yield succinic acid. For the details of the process for obtaining succinic acid from calcium malate, see the paper of E. J. Kohl, in *A. J. P.*, vol. xxviii, July. Succinic acid, when pure, is in white, transparent crystals having no odor and a somewhat acrid taste. It dissolves in five times its weight of cold and twice its weight of boiling water. It is less soluble in alcohol and very sparingly so in ether. Nitric acid is without action on it. It melts at 182° C. (359.6° F.), and boils without alteration at 235° C. (455° F.). It sublimes, however, at a much lower temperature. According to Wackenroder, it is sometimes adulterated with tartaric acid soaked in oil of amber. Succinic acid, though formerly official, is at present seldom used in medicine. It has been ascertained to be a product of vital action, having been detected by Heintz in the colorless liquid found in hydatid cysts of the liver. (See *J. P. C.*, Sept., 1850.) One of its salts, *ammonium succinate*, $(NH_4)_2C_4H_4O_4$, made by supersaturating succinic acid with ammonia, evaporating and crystallizing, has been used with alleged great success in *delirium tremens*. This salt is occasionally used as a precipitant of ferric oxide. For a description of *sodium succinate*, see page 1616.

Succus Pomorum. *N. F. IV. Fresh Apple Juice.*—"The freshly expressed juice of sound, ripe, sour apples, the fruit of cultivated varieties of *Pyrus Malus* Linné (Fam. *Rosaceæ*)." *N. F. IV.* Fresh apple juice is used in making the N. F. *Ferrated Extract of Apples.*

Sucramine.—This substance, which has been exploited in France as a new sweetening agent, is said to be simply the ammonium salt of saccharin.

Sulfogenol.—Crude mineral oil obtained from a bituminous shale, by dry distillation, is saturated with sulphur and sulphonated by means of strong sulphuric acid. *Sulfogenol* is the ammonium compound of this sulphonated product. It possesses the same properties as ichthyol, but with a less disagreeable odor and taste, and is soluble in water and alcohol.

Sulfosote. *Potassium creosotic-sulphonate*, or a mixture of *guaiacol- and cresol-sulphonates of potassium.*—Under its proprietary name, *sulfosote* is supplied in the form of a syrup, of which the *dose* is said to be, for the adult, three fluidrachms (11.25 mils). It has been used in various forms of pulmonic disease for the treatment of which creosote is advisable.

Sulphaldehyde. *Thioaldehyde. Thioacetaldehyde.*—It is made by the action of hydrogen sulphide upon acetaldehyde in aqueous solution. An oil is obtained which solidifies at low temperatures. According to Lusini (*Nouv. Rem.*, 1890), this substance acts on the lower animals as a powerful hypnotic.

Sulphaminic Acid. *Amido-sulphonic Acid.* NH_2SO_2OH.—This occurs as colorless crystals, freely soluble in water. Emmerich (*M. M. W.*, 1912), on the theory that the irritant toxin of *cholera* is nitrous acid, recommended the use of *sulphaminic acid* in the treatment of this disease. A tablespoonful of a one per cent. solution may be given every hour.

Sulphaminol. $C_6H_4\langle{}^{S_2}_{NH}\rangle C_6H_3.OH$. *Thio-oxydiphenylamine.*—This compound is made by the action of sulphur upon the salt of metaoxydiphenylamine. It is a greenish-yellow powder free from odor and taste, readily soluble in alkalies, more difficultly so in alkaline carbonates, quite insoluble in water. When heated it turns brown, and melts at 155° C. (311° F.). It is asserted that this substance is harmless (see a paper by Kobert, *Journ. de Méd.*, Sept., 1890), and that when taken internally it is split up in the organism into oxydiphenylamine and sulphuric acid compounds. It has been used as an antiseptic dusting powder. Various compound solutions of it have been employed as local applications to the mucous membranes of the nose and larynx, such as *sulphaminol menthol, s. eucalyptol*, etc. Internally, it has been given in *doses* of from four to five grains (0.26–0.32 Gm.); externally, it may be used in powder or oily solutions.

Sulphanilic Acid. *N. N. R.* 1917. $C_6H_4(NH)_2(HSO_3)$ 1 : 4. *Para-amino-benzene-sulphonic Acid.*—It occurs as colorless crystals, slightly soluble in water and insoluble in alcohol and ether and efflorescent in the air. Internally it has been recommended in the treatment of chronic *catarrh* in *doses* of 10 to 30 grains (0.6–2.0 Gm.), although it is of doubtful value. Its most important use is in Ehrlich's diazo-reaction for typhoid urine. Under the name of *Nizin*, tablets containing 0.13 gramme of sulphanilate of zinc are marketed and asserted to possess both astringent and antiseptic properties.

Sulphoform. *Triphenylstibine Sulphide.* $(C_6H_5)_3SbS$.—According to Kaufmann (*Ber. d. Chem. Ges.*, 1908, xli), this compound liberates its sulphur with extreme ease; hydrogen dioxide causes a separation of the sulphur and oxidization to sulphuric acid, and the antimony being oxidized to antimony oxide which combines with the sulphuric acid, this reaction taking place almost quantitatively at a temperature of 36° C. (96.8° F.). He states that *sulphoform* is more than one hundred times as efficacious as ordinary sulphur as a reducing agent. Joseph (*Derm. Cb.*, 1910, xiv) has found it a very useful remedy for *seborrheic alopecia*, and also of service in *eczema* and other *skin diseases*. He uses an ointment containing from five to twenty per cent. of sulphoform.

Sulpholeic Acid and Sulpholeates.—Sulpholeates or salts produced by the combination of alkalies with sulpholeic acid, have come into use on account of their ability to dissolve many substances or hold them in suspension as emulsifying agents. Sulpholeic acid is prepared as follows: Castor, almond or other fixed oil is gradually mixed with 30 or 40 parts of concentrated sulphuric acid, the mixture being cooled, if necessary, with ice, to prevent a rise of temperature above 50° C. (122° F.). The reaction, which at first is quite violent, is allowed to go on for from six to twelve hours, after which the mixture of acid and glycerin is decanted, the residue mixed with 100 parts of water, and this, after stirring, is also decanted. The resulting sulpholeic acid is converted into *alkaline sulpholeate* by the addition of a hydroxide or carbonate of the required alkali. From this combination pure sulpholeic acid is obtained by careful decomposition with sulphuric acid, and agitation with purified benzin or ether, which leaves the acid on evaporation pure and anhydrous. (*Ph. Rund.*, 1885, p. 154.) According to A. Mueller Jacobs, when concentrated and in as pure a state as possible, the sulpholeates, as

well as the free sulpho-acids themselves, mix readily and completely with a great variety of organic compounds, for instance with liquid hydrocarbons, particularly those of low boiling point, with chlorine, iodine, and bromine derivatives of the same, with ethers and alcohols, with organic sulphur compounds, such as carbon disulphide, oil of mustard, mercaptan, etc., and with all essential oils. They also dissolve varying quantities of sulphur, iodorform, solid hydrocarbons, such as naphthalene, naphthol, anthracene, and paraffin, the terpenes and camphenes. These liquid mixtures of sulpholeates and other bodies have the property of forming emulsions or even clear solutions with water. The limit of the miscibility (in form of emulsion) or solubility varies considerably, and depends both on the degree of concentration of the sulpholeate serving as a menstruum, and on certain little understood properties of the substances mixed with it.

This peculiar behavior of the sulpholeates and particularly of the sulpho-ricinoleate of alkalies, towards many otherwise insoluble or difficultly soluble substances, as well as their pronounced saponaceous character and the great readiness with which they take up and combine with liquids, is said to render them eminently suitable for various technical and medicinal uses.

The liquid alkaline salt which forms the solvent is termed *polysolve* by A. Mueller Jacobs, who believes that the sulpholeate mixtures will be found excellent solvents for substances the employment of which in a concentrated condition is accompanied by certain untoward effects, or may serve as vehicles in place of vaseline, oils, glycerin, etc., in perfumery, soap making or pharmacy. (*Am. Drug.*, 1884, p. 22.)

Sulphopyrine. *Antipyrine para-aminobenzene-sulphonate. Antipyrine Sulphanilate.*—It is a white, crystalline powder, without odor, readily soluble in water, insoluble in alcohol. Although originally introduced as a substitute for antipyrine, Neumann (*All. W. M. Z.*, 1906, p. 813) has found that this drug has the power of preventing the appearance of that congery of symptoms commonly known as *iodism*. It is also used in *coryza*. The *dose* he employed was fifteen grains (1 Gm.) three times a day.

Sulphoid. *Sulfidal. Colloidal Sulphur.*—It is made by passing hydrogen sulphide through a solution of sulphurous acid and has been used in the treatment of various *skin diseases* as a substitute for the ordinary form of sulphur. According to Joseph (*Derm. Ob.*, 1907), it is distinctly superior to the insoluble forms of sulphur. In *acne* he employed a paste or ointment containing 10 per cent. of *sulphoid* and 2 per cent. of salicylic acid, in *alopecia seborrheacia* and *eczema squamosum* a 10 per cent. solution in water either with or without glycerin.

Sulphur Iodide. *Sulphuris Iodidum. U. S. VIII, Br.* 1898. *Sulfur Iodatum. Ioduretum Sulfuris. Iodure de Soufre*, Fr. *Jodschwefel*, G.—This compound is chemically regarded as *iodine disulphide*, I_2S_2, or, as sometimes stated, *sulphur subiodide*. *Sulphur iodide* is in "brittle masses of a crystalline fracture and a grayish-black, metallic luster, having the odor of iodine and a somewhat acrid taste. Almost insoluble in water; soluble in about 60 parts of glycerin; very soluble in carbon disulphide. Alcohol, ether, and a solution of potassium iodide dissolve the iodine, leaving the sulphur. Continued boiling with water vaporizes all of the iodine, leaving about 20 per cent. of sulphur as residue. On exposing Sulphur Iodide to the air, it gradually loses iodine. On heating it, some iodine sublimes at first; at a somewhat higher temperature a sublimate is formed, containing both iodine and sulphur. At a still higher temperature, the whole is volatilized, leaving only a trace of residue. If 0.5 Gm. of finely pulverized Sulphur Iodide, together with 1 Gm. of potassium iodide, be dissolved in 20 mils of water (the sulphur separating), not less than 28 mils of tenth-normal sodium thiosulphate V.S. should be required for complete decolorization of the mixture, using starch T.S. as indicator." *U. S. VIII.*

The process of the U. S. VIII of the U. S. Pharmacopœia for this salt was as follows: "Washed Sulphur, *twenty grammes* [or 308 grains]; Iodine, *eighty grammes* [or 2 ounces av., 360 grains]. Mix the Sulphur and Iodine thoroughly by trituration; introduce the mixture into a flask, close the orifice loosely, and, by means of a water-bath, gradually and with occasional agitation apply a heat not exceeding 60° C. (140° F.), until the ingredients combine and become of a uniformly dark color throughout. Then increase the heat to the boiling point of the water, so as to fuse the mass. Should any Iodine have sublimed and condensed on the glass, incline the flask so as to combine the Iodine with the fused mass, and then pour the latter upon a porcelain plate or other suitable cold surface. When it is cold break the product into pieces of suitable size, and keep them in a glass-stoppered bottle, in a cool place." *U. S. VIII.*

Its solution in glycerin would probably prove useful, in some cases, as a substitute for the ointment of this iodide. It is rapidly decomposed, when in a state of powder, upon the addition of several of the volatile oils, violet vapors of iodine being evolved, and the odor of sulphur perceived. Sulphur iodide has been very usefully employed as an external remedy in various skin diseases, such as *tinea capitis, lupus, lepra*, etc., applied in the form of ointment. *Ointment of sulphur iodide*, formerly official in the British Pharmacopœia, was made by mixing together 1 part of sulphur iodide, one part of glycerin and 23 parts of benzoinated lard. Internally, it has been used with alleged advantage in human *glanders*. (Bourdon, of Paris, *Ann. Thér.*, 1858, 239.)

Sulphoricinic Acid.—This is made by the action of from 30 to 40 per cent. sulphuric acid upon castor oil at a temperature not exceeding 50° C. (122° F.), care being taken to avoid the evolution of sulphur dioxide. On the addition of water, sulphoricinic acid with unchanged oil separates in an oily layer from the aqueous solution of acid below. This substance is a powerful local irritant. Berliox states that the acid and its soluble salts are actively antiseptic and deodorizant; useful as a local application in *ozena* and other affections. (*S. M.*, March 11, 1891.) *Sodium sulphoricinate* is described on page 1616. The commercial product made by the action of strong sulphuric acid upon castor oil is known as *Turkey Red Oil*, and is used as a hydrolizing agent in the manufacture of fatty acids and glycerin from fixed oils by the so-called Twitchell process.

Sulphosalicylic Acid. *Salicyl-sulphonic Acid.* $C_6H_3SO_3H.OH.COOH$.—Made by acting upon salicylic acid with strong sulphuric acid. It is in the form of white acicular crystals, soluble in water and alcohol. *Sulphosalicylic acid* is used, like sodium salicylate, in rheumatism, but its chief value lies in its use as a reagent to detect the

presence of proteids of all kinds. Egg-albumin (1 in 12,500) can be detected by this reagent, forming a dense, white precipitate which is not redissolved on boiling. It is used to detect albumin, peptones, globulins and fibrin. Albumoses and peptones redissolve when boiled, but again separate on cooling.

Sweet Pellitory.—The root of *Tanacetum umbelliferum* Boiss. (Fam. *Compositæ*), of India, according to David Hooper, contains pyrethrine in minute proportions with fat and wax, an organic acid which is a pigment, glucose, and inulin. (*P. J.*, xxi, 1890.)

Swietenia. *Swietenia febrifuga* Roxb. (*Soymida febrifuga* Juss.) *Rohan Bark.* (Fam. *Meliaceæ.*)—The bark of this East Indian tree contains a bitter principle and is said to be much used as an antiperiodic in half drachm (2 Gm.) *doses*. The extract is used in *dysentery* like kino.

Swietenia Mahogoni Jacq., or *mahogany tree*, which grows in the West Indies and other parts of tropical America, has also a bitter, astringent bark, containing catechin. (*Bull. Soc. Chim. Paris*, xxiv, 118.) The oil of the seeds is said to be used as a purgative in the West Indies. The bark of *S. senegalensis* Desv. (*Khaya senegalensis* A. Juss.), *Juribali bark*, is used on the coast of Africa in the cure of *intermittents*, and Caventou extracted an alkaloid from it. (*Am. J. M. S.*, N. S., xx, 168.)

Symphorol. *Symphoral. Sodium, Lithium*, or *Strontium Caffeine-sulphonates.*—The name *symphorol* is applied to either of the salts above mentioned. They are colorless, odorless, bitter powders. The sodium salt is used as a diuretic in *doses* of fifteen grains (1 Gm.) several times a day.

Symphytum. *Symphytum officinale* L. *Comfrey. Blackwort. Briussewort. Radix Symphiti. Radix Consolidæ Majoris. Consoude*, Fr. *Schwarzwurz, Beinwurz*, G.—A perennial, European plant often cultivated. Its root is spindle-shaped, branched, often more than 2.5 cm. thick and 3 dm. long, externally smooth and blackish, internally white, fleshy, and juicy. By drying it becomes wrinkled, of a firm, horny consistence, and of a dark color within. It is almost inodorous, and has a mucilaginous, feebly astringent taste. Titherley and Coppin in 1912 found 0.8 per cent. of *allantoin*, $C_4H_6N_4O_3$, in the rhizome. It contains mucilage in great abundance (according to Lewis, more than althæa root), and a little tannin. It was formerly highly esteemed as a vulnerary. According to Macalister (*B. M. J.*, Jan. 6, 1912), *allantoin*, in aqueous solution in strengths of 0.3 per cent. has a powerful action in hastening epithelial formation, and is a valuable remedy not only in external ulceration, but also in *ulcers of the stomach* and duodenum. Comfrey is a demulcent, and is used domestically in *chronic catarrhs, consumption*, and other lung diseases.

Symplocos. *Symplocos racemosa* Roxb. (Fam. *Styraceæ.*)—The bark of this East Indian tree is said to be a mild astringent, and especially useful in *menorrhagia*. (*P. J.*, Sept. 24, 1881.)

Synanthrose. *Lævulin.* $C_6H_{10}O_5$.—This is a carbohydrate, isomeric with inulin, discovered by O. Popp in *Helianthus tuberosus* L. (fam. *Compositæ*). For details, see Tollens, *Kohlenhydrate*, 198.

Syringa. *Syringa vulgaris* L. *Common Lilac.* (Fam. *Oleaceæ.*)—The leaves and fruit of this common garden plant have a bitter and somewhat acrid taste, and have been used as tonics and antiperiodics. Petroz and Robinet found in the fruit a sweet and a bitter principle. The latter was afterwards obtained pure by Meillet, who gave it the name of *lilacin*, and by Bernays, who called it *syringin*. It has been investigated by Kromayer (*A. Pharm.* (2), cxiii, 19), who established its glucosidal character, gave it the formula $C_{17}H_{24}O_9 + H_2O$, and showed it identity with the *ligustrin* of Polex. It forms long, white, stellate needles, which are tasteless, easily soluble in hot water and alcohol, insoluble in ether. The crystals become anhydrous at 115° C. (239° F.), and fuse at 212° C. (413.6° F.). As an antipyretic and antiperiodic drug it is said to be very valuable, especially when administered in the relapsing fevers of *malaria*. On heating with dilute acids its breaks up into *syringenin*, $C_{11}H_{14}O_4$, and a fermentable glucose. The *syringenin* (which has been recognized as *oxymethyl coniferin*) is a light, rose-red amorphous mass, soluble in alcohol, insoluble in water and ether.

Syrup of Ferrous Bromide. *Syrupus Ferri Bromidi, U. S.* 1880. *Syrup of Bromide of Iron.*—"A syrupy liquid containing 10 per cent. of Ferrous Bromide. It is made from bromine and iron by a process analogous to that for syrup of ferrous iodide. Ferrous bromide has been recommended as a sedative chalybeate tonic, and has been especially praised by Jacob Da Costa in *chorea*. In an extended trial of it by H. C. Wood, it failed entirely to be of service. It is not an eligible chalybeate. *Dose*, of the syrup, from one-half to one fluidrachm (1.8–3.75 mils), equal to about four to eight grains of the bromide.

Tacamahac. *Tacamahaca.*—These names are applied to a resinous substance which is sometimes substituted for or admixed with Elemi resin. There are two classes of these products: (1) one having an odor resembling Elemi and including the *East Indian Tacamahac* which is probably obtained from *Calophyllum Inophyllum* L. (Fam. *Guttiferæ*), and *Bourbon Tacamahac*, obtained probably from *C. Tacamahaca* Willd. The West Indian and East Indian *Resin Anime* is a product of one of the Burseraceæ; (2) a second class having an odor of incense and including *Cayenne Incense*, obtained probably from *Icica heptaphylla* Aubl. (now *Protium heptaphyllum* March. (Fam. *Burseraceæ*), a West Indian Tacamahac obtained from *Protium heptaphyllum* and related species. There are also several gums and resins of this same character which are obtained from *Bursera gummifera* L. and other plants of the Burseraceæ. The resinous substance derived from *Bursera tomentosa* Triana, a tree of considerable size, of the Fam. *Burseraceæ*, growing in the island of Curaçoa and in Venezuela, is in irregularly shaped pieces of various sizes. The color is usually light yellowish or reddish-brown, but in the larger masses is more or less diversified. The pieces are in general translucent, though frequently covered with powder upon their surface, so as to render them apparently opaque. They are heavier than water, brittle, and pulverizable, yielding a pale yellow powder. Their odor is resinous and agreeable, their taste bitter, balsamic, and somewhat acrid. Exposed to heat, they melt and exhale a stronger odor. Tacamahac is partially soluble in alcohol, and completely so in ether and the fixed oils. It consists of resin with a little volatile oil.

The East Indian tacamahac and called *tacamahaca orientale*, or *tacamahaca in testis*, comes into the market in gourd shells covered with rush leaves. It is of a pale yellow color inclining to green, slightly translucent, soft, and adhesive, of an

agreeable odor, and an aromatic bitterish taste. It is at present very rare in commerce. The tree which yields this resin produces a drupe, about as large as a plum, from the seeds of which 50 per cent. of a greenish-yellow fixed oil is obtained by expression, which is used in India for lamps, and as a local application in the *itch*. (*J. P. C.*, 1861, 23.) Guibourt describes several other varieties of tacamahac, which, however, are little known. Among them is a soft, adhesive, dark, green oleoresin (*J. P. C.*, 3e sér., xxiv, 396), said to be procured from the *Calophyllum Tacamahaca* Willd., growing in the islands of Réunion and Madagascar. (See also Pennetier, *Matières Premières*, 642.)

Tacamahac was formerly highly esteemed as an internal remedy, but is now used only in ointments and plasters. Its properties are analogous to those of the turpentines. It is sometimes used as incense.

Tachia. *Tachia guianensis* Aubl.—The root of this tree (Fam. *Gentianaceæ*), is used under the name of *Caferana*, in Brazil, as an antiperiodic and tonic. According to Peckoldt it contains an organic, crystalline substance, *caferanine*. (See *Merck's Bericht*, 1889; also *Ber. d. Chem. Ges.*, 1899, No. 7.)

Taka Diastase.—This ferment discovered by Takamine is formed by the action of a fungus (*Moyashi; Aspergillus Oryzæ* Cohn., *Eurotium Oryzæ* Ahlburg; for description, see *A. J. P.*, 1898, 137) upon steamed rice, and is used in Japan, where it is known by the name of *koji*, in the preparation of the national intoxicating beverage *sake*. It has also been employed to act upon maize in the making of whisky. It is a yellowish-white, highly hygroscopic powder, almost tasteless, freely soluble in water. It is capable, under proper conditions, of converting one hundred times its weight of starch in ten minutes into glucose. Its action and therapeutic uses are the same as those of diastase from malt. (See p. 403.) It should be given in the middle of the meal, in *doses* of from five to ten grains (0.32–0.65 Gm.), in capsules; or, after the meal, in slightly alkaline solution.

Tamaquare.—A fluid preparation from a Brazilian Myrospermum, which is miscible with alcohol, does not dry and possesses an unctuous consistency. It is used in certain diseases of the eye, petrolatum being used as the vehicle. From a three to a ten per cent. ointment is the usual strength.

Tanformal.—This is claimed to be a chemical combination of tannin, phenol, and formaldehyde. It forms an aromatic, brown powder, insoluble in water and decomposed by alkalies. It is said to be insoluble in the acid gastric juice and soluble in the intestinal juices, and therefore useful as an intestinal astringent and antiseptic. *Dose*, eight to thirty grains (0.5–2.0 Gm.).

Tanghinia. *Ordeal Bean of Madagascar.—Tanghinia venenifera* Poir. (*Cerbera Tanghin* Hook.) (fam. *Apocynaceæ*), has been investigated, and, according to C. E. Quinquaud, is both a respiratory and a cardiac poison. (*C. R. A. S.*, cl, 534; see also *T. G.*, vol. ii, 610.) The active principle, *tanghinin*, occurs in colorless lustrous scales, efflorescing in the air, having a bitter and sharp taste, soluble in alcohol, ether, and acetic acid.

Tang-kui or **Man-mu.**—Under the name of *tangkui* the Chinese have used for a long time a root obtained from some umbelliferous plant closely allied to the *Levisticum officinale*, which, according to Lezenius (*Ph. Centralh.*, 1910, p. 221), is probably from the *Ligusticum acutilobum*. A fluidextract of this root has been introduced into European medicine under the name of *eumenol* and is recommended by a number of authors in the treatment of *dysmenorrhea* and other uterine complaints. The *dose* of this fluidextract is one tablespoonful three times a day. Bufalini, having searched in vain for an active alkaloid, believes that the activity of the substance depends upon an ethereal oil.

Tannalbin. *Tannin Albuminate. N. N. R.* 1917.—This compound, suggested by Gottlieb, is made by adding to ten parts of a 10 per cent. solution of albumin, six and a half parts of a 10 per cent. solution of tannin; the precipitate is collected, washed, pressed, and dried by exposure to heat (about 110° C., 230° F.) for six hours. It contains about one-half its weight of tannin. It is a light brown powder, insoluble in water and in the gastric juice, tasteless, odorless, and not at all irritant to the mucous membranes. As an astringent it is very feeble, but, as the tannic acid is probably liberated in the intestines, it is a valuable remedy in the treatment of *chronic diarrhea* dependent upon intestinal relaxation, and has even been used with asserted satisfaction when there were intestinal catarrh and ulceration. It does not disturb the digestion, but has been highly commended in *gastric catarrh* with excessive secretion of mucus. *Dose*, from fifteen to thirty grains (1–2 Gm.), three to six times a day, in capsule or powder.

Tannalum. *Tannal. Basic Aluminum Tannate.* $Al(OH)_2(C_{14}H_9O_9) + 5H_2O$.—This is a brownish-yellow powder, insoluble in water, which has been especially commended by Heymann as a mild, astringent, non-irritant substance, to be used as a dusting powder or by insufflation in diseases of the nasal and laryngeal mucous membranes. By the action of tartaric acid it becomes converted into the so-called *soluble tannal*, $Al(C_4H_4O_6)(C_{14}H_9O_9) + 3H_2O$, also used locally.

Tannargan. *Tanargentan.*—This compound occurs as a dark gray, insoluble powder. It is formed by the interaction of silver nitrate, albumen, and tannic acid, and is said to contain 10 per cent. of silver. It has been used as an intestinal disinfectant in cases of *gastro-enteritis*, *typhoid fever* and *intestinal tuberculosis*, but is employed more in veterinary than human practice. The *dose* for a man is four to eight grains (0.25–0.5 Gm.) two or three times a day.

Tannigen. *Tannyl Acetate. N. N. R.* 1917. $C_{14}H_8(COCH_3)_2O_9$.—This compound, which is prepared by the action of acetic anhydride or acetyl chloride upon tannin, is the diacetic ester of tannic acid. It is a yellowish-gray, tasteless and odorless, slightly hygroscopic powder, which can be heated to 180° C. (356° F.), without alteration; insoluble in cold water, readily soluble in alcohol, dissolving in diluted solution of sodium phosphate, soda, or borax, with the production of a yellowish-brown color. It has been used as a mild astringent in chronic *diarrheas*, *especially* in such as often accompany *phthisis*, and as a local application by insufflation in chronic *rhinitis* and *laryngitis*. *Dose*, from ten to fifteen grains (0.65–1.0 Gm.) three or four times a day, in capsules; to children it may be given spread on bread and butter.

Tannisol.—This is prepared by heating tannin with a 35 per cent. formaldehyde solution on a steam bath until a pulverizable mass results. It is then dried until all the excess of formaldehyde is driven off. It forms a reddish-brown powder, inodorous and tasteless, and soluble only in alkaline

fluids. Similar to other tannin preparations of this type it is used as an astringent antiseptic in *doses* ranging from two to eight grains (0.12–0.5 Gm.).

Tannobromine.—This is a reddish or yellowish powder, resulting from the action of formaldehyde on dibrom-tannin. It is sparingly soluble in water, readily so in alkaline solution or in alcohol. It is used in the treatment of *scalp diseases.*

Tannocasum.—Casein and tannin in combination in the form of yellowish, flaky powder constitute this product. It is employed largely as an intestinal astringent in *doses* ranging from eight to thirty grains (0.5–2.0 Gm.).

Tannochrom is found in commerce as a gray insoluble powder containing fifty per cent. of a compound of chromium bitannate and resorcinol; a fifty per cent. solution is also used which is miscible with water, alcohol and glycerin. The powder is used in the treatment of *eczema* and other skin diseases, and the liquid in one-fourth to one-half per cent. solution in *gonorrhea.*

Tannocol. *Gelatin-tannate.*—This is a tasteless, odorless powder, containing about 50 per cent. of tannic acid, having the same therapeutic properties and applications as tannalbin. It is claimed by Rosenheim that it is superior to that substance in being cheaper, of greater constancy of constitution, and less easily affected by the gastric juices. In the intestines it is decomposed by the alkaline secretions and tannic acid is liberated. *Dose,* fifteen to thirty grains (1–2 Gm.).

Tannoform. *N. N. R.* 1917. *Helgotan. Methylene Ditannin.* $CH_2(C_{14}H_9O_9)_2$.—A new class of bodies has been prepared by Merck which are termed *tannoforms,* and which consist of combinations between the various characteristic tannins and formaldehyde. These bodies are formed by adding a solution of formaldehyde gas to a purified plant extract containing the plant tannin, in the presence of hydrochloric acid. The further nomenclature of the tannoforms depends upon the name of the plant from which the particular tannin is derived.

The condensation product of gallotannic acid and formaldehyde, which is termed simply tannoform, is made by dissolving five grammes of tannin in about fifteen kilogrammes of hot water, adding three kilogrammes of 30 per cent. formaldehyde, and then adding concentrated hydrochloric acid until no further precipitate is thrown down. This requires about twelve to fifteen kilogrammes of acid. The precipitate is then washed with water and dried at a low temperature.

Tannoform occurs as a light, pinkish powder which decomposes at about 230° C. (446° F.). It is dissolved by alcohol and is insoluble in all the usual organic solvents; but is soluble in diluted ammonia, sodium or potassium hydroxide solutions, giving a brownish-red solution, from which it is again precipitated upon the addition of an acid. When warmed with concentrated sulphuric acid it dissolves with a brown color, turning on further heating to green, and then to blue. This green or blue solution gives a blue color with alcohol, which on standing some time turns to a wine-red, and on dilution with soda solution to a grass-green color.

Tannoform has been used with alleged good results in *enteritis* and other forms of *diarrhea.* It is asserted that the drug is decomposed by the intestines, the tannic acid radical acting as an astringent, and the formaldehyde as an antiseptic. It is, however, more frequently employed as a local remedy in the treatment of *eczema, bed sores,* etc. In *hyperidrosis of the feet,* well rubbed in between the toes over night, it will often give relief of considerable duration, but has the disadvantage of staining the skin brown. It has also been used externally to control night sweats. *Dose,* from five to fifteen grains (0.32–1.0 Gm.), in capsule, from three to six times a day.

Tannoguaiaform is a compound of tannic acid, guaiacol and formaldehyde. It is odorless and tasteless and has been recommended as an intestinal astringent and antiseptic particularly suited to the treatment of intestinal tuberculosis, as it probably liberates formaldehyde in the intestines. Care should be used in prescribing it. *Dose,* eight to fifteen grains (0.5–1.0 Gm.).

Tannon. *N. N. R.* 1917. *Tannopin,* $(CH_2)_6N_4(C_{14}H_{10}O_9)_3$, is a condensation product of tannin and hexamethylenetetramine. It is a light brown, tasteless and odorless, non-hygroscopic powder, insoluble in water, weak acids, spirit, and ether, but dissolving slowly in dilute alkaline solution. It has been used by Schreiber (*D. M. W.,* 1897) in *diarrhea* in *doses* of fifteen grains (1.0 Gm.) from three to four times a day.

Tannosal. *Creosote Tannate. Creosal.*—While the manufacturers of this preparation claim that it is a definite chemical compound yet it has been stated that it is a simple mixture of creosote and tannic acid. It occurs as a brown, amorphous powder, soluble in water, smelling slightly of creosote and containing about 60 per cent. of the latter. It splits up into its constituents in the small intestine and is consequently proposed as a valuable remedy in the treatment of *phthisis. Dose,* five to twenty grains (0.33–1.3 Gm.).

Tannothymal.—This substance which is a condensation product of thymol, formaldehyde and tannin, occurs as a yellowish to reddish powder, practically insoluble in water and dilute acids, but decomposed by dilute alkalies.

It has been used as an astringent antiseptic in the treatment of *diarrhea.* The *dose* is eight to fifteen grains (0.5–1.0 Gm.) three times a day.

Tannyl.—It is said to be a compound of tannin with oxychlor-casein. It is a grayish-brown powder, insoluble in water, and unaffected by the gastric juice.

According to Salkowski, oxychlor-casein has a marked action as an intestinal disinfectant, but by itself is not useful, because it is destroyed by the gastric juice. Combined with tannin, however, it is capable of reaching the intestinal tract in a still active form. Umber (*Ther. Geg.,* 1908) has used *tannyl* with asserted success in the treatment of *diarrhea,* not only when due to ordinary *enteritis,* but even in tuberculous cases.

The *dose* of tannyl is from fifteen to forty-five grains (1–3 Gm.).

Tansy. *Tanacetum. U. S.* 1890.—Under this name the U. S. Pharmacopœia formerly recognized the tops and leaves of the *Tanacetum vulgare* L., a perennial herbaceous plant rising two or three feet in height, which is cultivated in our gardens, although growing wild in the roads and in old fields. It was originally introduced from Europe. It is in flower from July to September.

Tansy was officially described as follows: "Leaves about 15 Cm. long; bipinnatifid, the segments oblong, obtuse, serrate or incised, smooth, dark green, and glandular; flower-heads corymbose, with imbricated involucre, a convex, naked receptacle, and numerous yellow, tubular florets." *U.*

S., 1890. The odor is strong, peculiar, and fragrant, but much diminished by drying; the taste is warm, bitter, somewhat acrid, and aromatic. These properties are imparted to water and alcohol. According to Leppig (*Inaug Dis.*, Dorpat, 1882), both the flowers and the leaves contain the following constituents: *tanacetin*, tannic acid (*tanacetum-tannic acid*), traces of gallic acid, volatile oil, a wax-like substance, albuminoids, tartaric, citric, and malic acids, traces of oxalic acid, a lævogyrate sugar, resin, metarabic acid, parabin, and woody fiber. Of these the most important are the bitter principle *tanacetin*, to which Leppig gives the formula $C_{11}H_{16}O_4$, and which forms a very hygroscopic, brownish, amorphous mass, easily soluble in alcohol and in water, insoluble in ether. It possesses a taste at first characteristically bitter like willow bark, and then cooling and caustic. The essential oil was investigated by Bruylants (*Ber. d. Chem. Ges.*, xi, 449), according to whom it consisted of a terpene, $C_{10}H_{16}$, boiling at from 155° to 160° C. (311°–320° F.), of which 1 per cent. only is present, an aldehyde, $C_{10}H_{16}O$, boiling at from 195° to 196° C. (383°–384.8° F.), of which 70 per cent. was obtained, and an alcohol (borneol), $C_{10}H_{18}O$, boiling at from 203° to 205° C. (397.4°–401° F.), of which 26 per cent. was present. Semmler (*Ber. d. Chem. Ges.*, xxv, 3343, 3352, 3513) has specially investigated the constituent boiling at 195° C. (383° F.), and having the composition $C_{10}H_{16}O$. He finds it to be not an aldehyde, but a ketone, and calls it *tanacetone*. It is identical with the ketone found in sage oil, wormwood oil, and thuja oil. As it was first identified in this last-named oil by Wallach, and named by him *thujone*, this name is now applied to it to the exclusion of the other. (See also *Schim. Rep.*, April, 1893, and April, 1897; and Gildemeister and Hoffmann, *Aetherische Oele.*)

Tansy adds to the medicinal properties of the aromatic bitters those of an irritant narcotic. It has been recommended in *intermittents*, *hysteria*, and *amenorrhea*, but in this country is little employed in regular practice. The seeds are said to be most effectual as a vermifuge. Tansy has been used to a considerable extent as a domestic abortifacient, but is not only very uncertain, but also very dangerous in its action, and has in varicus cases produced death. The symptoms caused by it have been abdominal pain, vomiting, violent epileptic convulsions often followed by profound coma, dilated pupils, great disturbances of respiration, frequent and feeble pulse, and death, which has been said to be from heart failure, but is probably the outcome of a paralytic asphyxia. The minimum fatal dose can scarcely be considered to have been positively ascertained, but a fluidrachm (3.75 mils) of the oil is said to have caused death, although recovery in one case occurred after taking half a fluidounce. Tansy tea has also caused death. (For cases, see *Am. J. M. S.*, xvi, xxiii, xxiv; *J. P. C.*, April, 1870; *J. A. M. A.* xlvii, p. 509.) Post-mortens have been reported in which no inflammation of the gastro-intestinal mucous membranes could be discovered.

The *dose* of the powder is from thirty grains to a drachm (2.0–3.9 Gm.) two or three times a day; but the infusion is more frequently administered.

Tapioca.—Under this name the U. S. P. formerly recognized the starch grains obtained from the bitter cassava (*Manihot utilissima* Pohl), and the sweet cassava (*M. palmata* var. *Aipi* Pohl) (Fam. *Euphorbiaceæ*). The starch is extracted from the thickened root and is known in commerce by the names of *Cassava*, *Tapioca* or *Manioca Starch*, and as *Bahia*, *Rio* or *Para Arrowroot*. The plant is cultivated in Brazil and other parts of tropical America. It is also grown in Florida and other of the Southern States. In the production of the starch from the bitter cassava the hydrocyanic acid which is present in fresh roots is entirely eliminated by the process of washing and drying.

The root of the *sweet* cassava may be eaten with impunity; that of the *bitter*, which is the most extensively cultivated, abounds in an acrid, milky juice, which renders it highly poisonous if eaten in the recent state. Henry and Boutron Chalard affirm that the bitter cassava contains hydrocyanic acid (*J. P. C.*, xxii, 119), but Peckdolt claims that its poisonous effects are due to *manihotoxine* (*Ph. Rund.*, iv, 1890).

The preparation of tapioca in Malacca is thus described by James Collins: The fresh rootstocks are thoroughly washed in tubs in a constant stream of water by the Chinese, and then peeled like turnips; they are then sliced in one machine and pulped in another, the pulp being removed in cane baskets to large wooden frames, with calico bottoms; a powerful stream of water is allowed to fall upon the pulp, a sifting motion being communicated to the strainer; as the starch is washed out, it is received into inclined troughs, and, while in a state of suspension, run into settling vats. There it is stirred and washed, and, while moist, it is removed to the drying room. Two kinds of tapioca are prepared. The flour is made by heating slightly by fires placed underneath; it is constantly stirred and turned over with iron shovels, to prevent agglutination and insure equal drying. Granular tapioca is made as follows: A long range of quallies, or small, shallow iron pans, are slightly tilted forward on ledges of brickwork, and heated with a wood fire. Each operator has a quallie and fire to himself. Taking a quantity of damp starch, he stirs it round and round with an iron shovel, and the heat is sufficient to cause the tapioca to become agglutinated together in small masses, and coated with dextrin. The drying is done with great skill over an open fire. (*C. D.*, 1884.)

Tapioca is in irregular, hard, white, rough grains, possessing little taste, partially soluble in cold water, and affording a fine blue color when iodine is added to its filtered solution. The partial solubility in cold water is owing to the rupture of the starch granules by heat. Examined under the microscope, the granules appear somewhat plano-convex or bell-shaped and more or less compound. The individual grains vary from 0.006 to 0.030 mm. in diameter and have a distinct central circular or radiating cleft. They polarize light strongly, showing a distinct cross. *Tapioca meal*, called sometimes *Brazilian arrow-root*, and by the French *moussache*, is the fecula dried without heat. Its granules are identical with those already described. Being nutritious, and the same time easy of digestion and destitute of irritating properties, tapioca forms an excellent diet for the sick and convalescent. It is prepared for use by boiling it in water. Lemon juice and sugar are usually grateful additions, and in *low states of disease* or cases of *debility* it may be impregnated with wine and nutmeg or other aromatic.

A factitious tapioca is found in commerce, consisting of very small, smooth, spherical grains, and

supposed to be prepared from potato starch. It is sold under the name of *pearl tapioca.*

Cassaripe is the thickened gum obtained from the root of the bitter cassava, which is said to be innocuous and so actively antiseptic as to be habitually used in Brazil for the preservation of meat. According to S. D. Risley (*Phila. Med. Journ.*, 1899), the 10 per cent. ointment of cassaripe is useful in *suppurating conjunctivitis* and *ulcers* of the *cornea*, applied with gentle massage three or four times a day.

Taxus. *Taxus baccata* L. *Yew Tree. If commun*, Fr. *Eibe*, G. (Fam. *Taxaceæ.*)—The fruit of this handsome evergreen appears to be a deadly poison. In a fatal case the child was found semicomatose, with convulsions, a cold and clammy skin, difficult respirations, dilated pupils, and making attempts at vomiting. The poison is probably in the seeds. (See 16th edition, *U. S. D.*; also James Thompson, *L. L.*, 1868, 530. For fatal cases in adults, see *M. T. G.*, 1870, ii; also *L. L.*, 1870, 471; also *P. J.*, viii, 361.) W. Marmé obtained from yew seeds and leaves an alkaloid, $C_{37}H_{51}NO_{10}$, to which the name of *taxine* has been given. It was a white, poisonous, crystalline powder, only slightly soluble in water, easily soluble in ether, alcohol, chloroform, benzene and carbon disulphide, but not in petroleum benzin. It fused at 80° C. (176° F.). With concentrated sulphuric acid it gave a red color, but dissolved without color in nitric and phosphoric acids. (*A. J. P.*, 1876, 353.) For Vreven's method of isolating taxine, see *P. J.*, 1896, 215. Amato and Capparelli (*Gazz. Chim.*, x, 349) prepared from the leaves a volatile alkaloid, which was soluble in cold sulphuric acid with yellow color, becoming red on heating. They also isolated a nitrogenous crystalline and colorless principle, fusing at from 86° to 87° C. (186.8°–188.6° F.), soluble in alcohol, insoluble in water, named *milossin.*

Lefebvre (*A. Pharm.*, ccxlv, 486) has isolated from the twigs of the yew a crystalline glucoside to which he gives the name "*taxicatin.*" It had the formula of $C_{13}H_{22}O_7 + 2H_2O$ and a melting point of 165° C. (329° F.).

Tayuya.—The root of the *Dermophylla* (*Cayaponia*) *pendulina* Manso (Fam. *Cucurbitaceæ*), is used in Brazil, under the name of *tayuya*, in *syphilis*, etc. (*N. R.*, 1877, 234); also, under the same name, the root of the *Trianosperma ficifolia* Mart. (*Cayaponia Martiana* Cogn.), also of the Fam. *Cucurbitaceæ* (*P. J.*, x, 667), and probably various other roots. In *C. ficifolia* Cogn. two alkaloids, *trianospermine* and *trianospermitine*, and a bitter principle, *tayuyin*, have been found by Peckoldt (*P. J.*, x, 667), and in *T. dermophylla* a green resin, bitter extractive, and tannic acid were found by the same investigator. (*B. G. T.*, lxxxiv, xci. See also *Proc. A. Ph. A.*, xxiv.)

Tea. *Thé*, Fr. *Thee*, G.—The plant which furnishes *tea—Thea sinensis* L. (Fam. *Theaceæ*)—is an evergreen shrub. It has numerous alternate branches, furnished with elliptical-oblong or lanceolate, short petiolate, pointed leaves, which are serrate except at the base, smooth on both sides, green, shining, pinnately veined and having a prominent midrib. They are two or three inches long, and from half an inch to an inch in breadth. The flowers are either solitary or supported, two or three together, at the axils of the leaves. They are of considerable size, not unlike those of the myrtle in appearance, consisting of a short green calyx with five or six lobes, of a corolla with from four to nine large unequal snow-white petals, of numerous stamens with yellow anthers and connected at their base, and of a pistil with a three-parted style. The fruit is a three-locular and three-seeded capsule.

There are two principal varieties of *T. sinensis*, viz. *viridis* L., which is a large spreading shrub, having light green lanceolate leaves from 12 cm. long to 4 cm. wide; and a second variety, *Bohea* L., which is an upright shrub with dark-green elliptical leaves 6 cm. long and 3 cm. wide. The flowers of the latter occur in groups of two or three, whereas in *viridis* they are single. There are a great many varieties of tea, on the market, and their trade value is influenced by the peculiarities of mother plant and climate and the degree of ripeness and preparation of the leaves. As a rule only the youngest leaves are gathered. The so-called black and green teas are due to the method of preparation of leaves. In the first the chlorophyll is destroyed, whereas in the latter it is unaffected. Winton gives the following characters as common to all tea leaves: "The firm, rather thick texture; the glossy upper surface; the short stem into which the base of the leaf tapers; the thick margins, rolled a little towards the inner surface, with cartilaginous teeth; the veins which branch from the midrib at angles usually greater than 45 degrees, and at some distance from the margin form loops uniting adjoining ribs. The teeth on the margin of the leaf are shrunken multicellular glands which break off readily from the old leaves." (For discussion of microscopical characteristics, see Winton and Moeller, "The Microscopy of Vegetable Foods."

The tea plant is a native of China and Japan, and is cultivated in both countries, but most abundantly in the former. It has been more recently cultivated in India (Assam), Ceylon, Java and in South Carolina. In Japan it forms hedge rows around the rice and corn fields; in China, whence immense quantities of tea are exported, whole fields are devoted to its culture. It is propagated from the seeds. For particulars as to the cultivation of tea, see *P. J.*, 1871, 386.

(An elaborate article on tea, with methods of cultivation, etc., by Wm. B. Marshall, U. S. Nat. Museum, will be found in *A. J. P.*, 1903, p. 79.)

The odor of the tea leaves themselves is very slight, and it is customary to mix with them the flowers of certain aromatic plants, as those of the orange, different species of jasmine, the rose, *Osmanthus fragrans* Lour. (*Olea fragrans* Thumb.), of the *Oleaceæ*, and *Camellia Sasangua* (Thumb.?), in order to render them pleasant to the smell. The flowers are afterwards separated by sifting or otherwise. (See *P. J.*, xv, 112.) Under the name of *flowers of tea* was at one time sold a waste product consisting of the hair of young leaves, but the flowers themselves have been used to make a beverage. (*P. J.*, lxxi, p. 453.)

Bush Tea and *Honig Thee*, used at Cape Colony, South Africa, as a substitute for tea, are the dried leaves and tops of several species of *Cyclopia*, among which are *C. subternata* Vog., *C. latifolia* DC., *C. genistoides* Vent. and *C. sessiliflora* Eckl. and Zeyh. (Fam. *Leguminosæ.*) According to the analysis of Henry G. Greenish, they do not contain theine, but a glucosidal body, *cyclopin*, $C_{25}H_{28}O_{13}$. (*P. J.*, xi, 549.)

The United States imported in 1915, 96,987,942 pounds of tea, valued at $17,512,619. The largest consumer is the United Kingdom, which in 1914 took 317,664,000 pounds, and the next Russia,

which took 166,064,003 pounds. Numerous varieties exist in commerce, differing in the shape communicated by rolling, in color, in flavor, or in strength; but they may be all arranged in the two divisions of *green* and *black teas*, which, at least in their extremes, differ so much in properties that it is difficult to conceive that they are derived from the same species.

Under the name of *tea oil* there has appeared in the London markets a Chinese fixed oil said to be derived from *Camellia drupifera* Lour. (*C. oleifera* Wall.), a detailed description of which, with tests, may be found in the *P. J.*, vol. xvi, 634. A similar oil is prepared in Japan from the seeds of *Camellia japonica* L. (*Ibid.*, 637, 764.)

Green tea is characterized by a dark green color, sometimes inclining more or less to blue or brown. It has a peculiar, refreshing, somewhat aromatic odor, and an astringent, slightly pungent and agreeably bitterish taste. Its infusion has a pale greenish-yellow color, with the odor and taste of the leaves. According to Warington, who examined numerous varieties of tea carefully, both by the microscope and chemical tests, many of the green teas imported into Great Britain owe their color to a powdery coating, consisting of calcium sulphate and Prussian blue; others to a mixture of these with a yellowish vegetable substance; and others, again, to calcium sulphate alone. (*P. J.*, iv, 37.) *Black tea* is distinguished by a dark brown color. It is usually less firmly rolled and lighter than the green, and contains the petioles of the plant mingled with the leaves. Its odor is fainter, and of a somewhat different character, though still fragrant. Its taste, like that of green tea, is astringent and bitterish, but is less pungent, and to many persons less agreeable. To hot water it imparts a brown color, with its sensible properties of taste and odor. These vary exceedingly in degree in the different varieties, and some black teas are almost wholly destitute of aromatic or agreeable flavor. According to Blyth, green tea is prepared from young leaves which are roasted over a wood fire within an hour or two after being gathered; while the black tea leaves, on the other hand, are allowed to lie in heaps for ten or twelve hours after they have been plucked, during which time they undergo a sort of fermentation; the leaves then pass through certain processes, and are slowly dried over charcoal fires. (Wynter Blyth, *Foods, Composition and Analysis*, 1903.) A sophisticated tea is largely exported from China, consisting of powdered tea mixed with sand and other earth, and agglutinated with gum; that which is to pass for black being colored with plumbago, and the green with the coating above referred to. On analysis, these teas were found to afford from 35 to 45 per cent. of ashes, while the genuine yields only 5 per cent. A very full account of the adulteration of tea and the methods for the detection of the same may be found in Allen, *Com. Org. Anal.*, 2d edition.

The analyses below[1] by Y. Kozai (*Bulletin No. 7, Imperial College of Agriculture*, Japan) have a special value, owing to the author's knowledge of tea manufacture. Unusual precautions were taken in sampling the leaves, to insure strictly parallel specimens being taken. The figures refer to the moisture-free leaves in each case.

[1] Analyses of Tea (percentage composition).

	Unprepared Leaves.	Green Tea.	Black Tea.
Caffeine or Theine	3.30	3.20	3.30
Ether Extract	6.49	5.52	5.82
Hot-water Extract	50.97	53.74	47.23
Tannin (as Gallotannic Acid)	12.91	10.64	4.89
Other Nitrogen Free Extract	27.86	31.43	35.39
Crude Protein	37.33	37.43	38.90
Crude Fiber	10.44	10.06	10.07
Ash	4.97	4.92	4.93
Albuminoid Nitrogen	4.11	3.94	4.11
Caffeine Nitrogen	0.96	0.93	0.96
Amido-nitrogen	0.91	1.13	1.16
Total Nitrogen	5.97	5.99	6.22

Rochleder found also a peculiar acid, which he calls *boheic acid*, $C_7H_{10}O_8$. According to Stenhouse, the tannin of tea, though always accompanied by a little gallic acid, differs essentially from that of galls; not being, like it, a glucoside, but yielding, under the influence of sulphuric acid, a dark brown substance, almost insoluble in water. (See *A. J. P.*, 1862, 254.) For article on the methods of analysis of tea and a series of analyses of different varieties, see *A. J. P.*, 1887, 626. The volatile oil is citron-yellow, lighter than water, has a strong odor of the tea plant, solidifies easily by cold, and resinifies on exposure to air. It is probably one of the principles upon which depend the effects of tea upon the nervous system. Hence old teas are less energetic than the recently imported; and it is said that the fresh leaves have often produced dangerous effects in China. Nevertheless, the tannic acid is not without influence upon the system; and it is not improbable that the extractive contributes to the peculiar influence of this valuable product. Of these active ingredients, the volatile oil, tannic acid, and extractive are found most largely, according to the analysis of Mulder, in the green tea. *Theine*, $C_8H_{10}N_4O_2$, is a crystallizable principle discovered by Oudry. It was afterwards proved by Jobst to have the same composition as caffeine (see page 247). Kossel discovered, in 1888, a related principle, *theophylline* (*dimethylxanthine*), but only in very small amounts. It is now made synthetically and is official. (See *Theophyllina.*)

The proportion of theine found in tea varies considerably, the general range being from three to four per cent. India and Ceylon tea usually contain slightly more than four per cent.

Tea is astringent and gently excitant, and exerts a decided influence over the nervous system, evinced by the feelings of comfort and even exhilaration which it produces, and the unnatural wakefulness to which it gives rise when taken in unusual quantities or by those unaccustomed to its use. It is almost exclusively used as a beverage. Taken moderately, and by healthy individuals, it may be considered as practically harmless; but long continued in excessive quantity it is capable of inducing unpleasant nervous and dyspeptic symptoms. Green tea is decidedly more in-

jurious in these respects than black, and should be avoided by dyspeptic individuals, and by those whose nervous systems are peculiarly excitable. It is rarely used as a medicine, but the infusion is popularly employed to relieve neuralgic headaches.

Tegmin.—Under this name a surgical dressing has been recommended; it is an emulsion made from yellow wax, one part; acacia, two parts; water, three parts; it also contains 5 per cent. of zinc oxide and a little wool fat. It is used as a protective and vehicle for skin remedies.

Telfairia Pedata Hook. (Fam. *Cucurbitaceæ.*)—The seeds of this East African plant yield a deep yellow fragrant oil, of specific gravity 0.918, containing *telfairic acid.* (*Chem. Zeit. R.*, xxiv, 24.)

Tellurium. (Te. Atomic weight, 127.5.)—The first physiological investigations as to the action of tellurium were made by Hansen (*Chem. Gaz.*, 1854), who found that the *potassium tellurate* produces in dogs vomiting, with stupor, and that in the dose of one grain three times a day it causes in man cardiac oppression, nausea, some salivation, with a pronounced garlic-like odor of the breath. These investigations have been extended and confirmed by William J. Gies (*M. A.*, June, 1901), who found that in doses of one-third of a grain per kilogramme sodium tellurate caused in the dog vomiting, diarrhea, unconsciousness, paralysis, convulsions, and death, with pronounced inflammatory changes in the intestines and kidneys similar to those seen after arsenic. Characteristic was the pigmentation of all parts of the body by metallic tellurium. During life the brown or greenish discoloration of urine and the very pronounced garlicky odor of the breath were almost diagnostic. The continuous administration of minute doses had no effect upon metabolism, but if the amount ingested was increased, gastro-intestinal irritation with restlessness soon appeared. Tellurium was found in the feces, urine, breath, and skin secretions. In man drowsiness, nausea and constipation seemed to result from the remedy, given in doses up to half a grain. There was also a marked anhidrotic action, even in healthy men, appearing fifteen minutes to one hour after the ingestion of the dose. Potassium tellurate is an efficient remedy for the arrest of *colliquative sweating*, but the pronounced alliaceous odor which it imparts to the breath, and even to the perspiration, greatly interferes with its use. *Dose* of potassium or sodium tellurate, one-sixth to one-half of a grain (0.01–0.032 Gm.).

Tellurous acid and its potassium salt have been recommended by Gosio (*Zeit. Hyg. u. Inf.*, 1905, li, 65) as an indicator of the presence of living bacteria, especially in sera. He asserts that it is harmless to the human and is reduced by growing bacteria giving rise to color change.

Tephrosia. *Tephrosia virginiana* (L.) Pers. *Turkey Pea. Wild Pea. Catgut. Goat's Rue. Hoary Pea. Devil's Shoestring. Tephrosie*, Fr., G. (Fam. *Leguminosæ.*)—Several species of *Cracca* and *Tephrosia* are employed in different parts of the world, though unknown in general commerce. They are leguminous plants, shrubby or herbaceous, with odd-pinnate leaves and white or purplish racemed flowers. They are generally possessed of cathartic properties, their leaves or roots being employed. Plugge (*Proc. A. Ph. A.*, 1897, 560) examined the root of *T. macropoda* and found a poisonous active principle, not identical with cytisine.

Hanriot isolated from *T. vogellii*, a crystalline principle, *tephrosin*, which occurs in small glistening crystals which are almost insoluble in water, slightly soluble in alcohol or glycerin, more readily soluble in acetone, and freely soluble in chloroform. Its formula is $C_{34}H_{26}O_{10}$. *Tephrosal*, $C_{10}H_{16}O$, is a volatile, aromatic liquid, slightly soluble in water, more readily soluble in alcohol, ether, benzin, and chloroform. (*T. C.*, li, 302.)

Tephrosia virginiana L. grows in most parts of the Eastern United States. It is a foot or two high, with pubescent stems and leaves and handsome terminal flowers. (See Griffith's *Med. Bot.*, 237.) The roots, which are slender, long, and matted, are tonic and aperient, and are said to have been used by the Indians as a vermifuge, given in the form of decoction.

According to Holmes (*P. J.*, 1910, lxxxiv) the *T. vogelii* is used in Africa as a fish poison. Its toxicity seems to be due to the neutral principle, *tephrosin*. There is no evidence as to its noxiousness for human beings.

Terpinol.—This is not a simple body, but a mixture of terpenes with variable proportions of an alcohol, *terpineol*, $C_{10}H_{17}OH$. It forms a colorless oily substance with a hyacinthine odor; it is produced by boiling terpin with diluted mineral acids. It is insoluble in water, but readily soluble in alcohol and ether. Terpinol has been used in chronic *bronchial catarrh*, and is especially commended by Lazarus when there is much irritation of the membrane with scanty secretion. Janowsky states that it is a valuable remedy in *hemoptysis*. The *dose* is three to five minims (0.2–0.3 mil) at intervals of from one to four hours, administered in capsules.

Terraline. *Terroline.*—A liquid proprietary petroleum product, odorless and tasteless, used internally in emulsions, in the *dose* of from one to two fluidrachms (3.75–7.5 mils). See *Petrolatum Liquidum* (Part I).

Testa Præparata. *Prepared Oyster-shell. Magistère de Coquilles (d'écailles) d'Huîtres*, Fr. *Präparirte Austerschalen*, G.—"Take of Oyster-shell *a convenient quantity*. Free the Oyster-shell from extraneous matter, wash it with boiling water, and, having reduced it to a fine powder, treat this in the manner directed for Prepared Chalk." *U. S.*, 1870. Prepared oyster-shell differs from prepared chalk in containing animal matter, which, being very intimately blended with calcium carbonate, is supposed by some physicians to render the preparation more acceptible to a delicate stomach. It is given as an antacid in *diarrhea*, in the *dose* of from ten to forty grains (0.65–2.6 Gm.) or more, frequently repeated. A preparation was introduced into use in this country, under the name of *Castillon's powders*, consisting of sago, salep and tragacanth, each, in powder, *a drachm*, prepared oyster-shell, *a scruple*, and sufficient cochineal to give color to the mixture. A drachm of this is boiled in a pint of milk, and the decoction used *ad libitum* as a diet in chronic bowel affections.

Tetra-ethyl Ammonium Hydroxide. $N(C_2H_5)_4OH$.—This occurs as colorless hygroscopic crystals, alkaline in reaction and is used in *articular rheumatism* and *uric acid diathesis*. The 10 per cent. solution is used in *doses* of five to twenty minims (0.3–1.3 mils).

Tetragastris. *Tetragastris panamensis* (Engl.) O. Kuntze. *Bois Cochon*, or *Sucrier de Montagne*, Fr. (Fam. *Burseraceæ.*)—This native of Panama has been examined by Gaucher, Combemale and

Marestang (*France Méd.*, October, 1888), who find in it an alkaloid and a resin. The extract of the root and stems produces in the guinea pig rapid and considerable lowering of temperature, progressive paralysis, general convulsions, dilatation of the pupils, respiratory irregularity and cardiac paresis. The alkaloid was found to be a convulsive agent, acting upon the spinal cord. The resin, which seemed much more active than the alkaloid, acted as a paralyzant.

Tetramethylammonium. $N(CH_3)_4$.—Several salts of this base have been prepared. *Tetramethyl ammonium hydroxide*, $N(CH_3)_4.OH$, occurs in deliquescent crystals which are freely soluble in both water and alcohol, but it is usually marketed in the form of a 10 per cent. solution. This caustic alkaline liquid has a strong affinity for carbon-dioxide. It has been used in *rheumatism* in *doses* of ten to fifteen minims (0.6–0.9 mil.). Tetramethylammonium bromide, chloride, and iodide have been made.

Tetranthera.—From the bark of the lauraceous plant, *T. citrata* Nees (now *Litsea citrata* Blume), J. D. Filippo has extracted an alkaloid, *laurotetanine*. (See *A. Pharm.*, 1898, 601.)

Charabot and Lalone examined the volatile oils from various parts of *Tetranthera* (*Litsea citrata*). The oil from the bark has the sp. gr. 0.8673 at 15° C. (59° F.), that from the leaves 0.9013 at 15° C. (59° F.) and that from the fruits 0.8872 at 15° C. (59° F.). (*P. J.*, 1908, 351.)

Tetronal. *Diethyl-sulphone-diethyl-methane.* $(C_2H_5)_2C(C_2H_5SO_2)_2$.—This occurs as a white crystalline powder, insoluble in water, soluble in alcohol and fusing at 85° C. (185° F.). The effects of this compound are practically the same as the closely allied *Sulphonethylmethane*. (See p. 1080.) Although the introducers of this group of drugs, Baumann and Kast (*A. E. P. P.*, 1892, xxxi) classed tetronal as the most powerful of the group it has failed to achieve the popularity of the official representatives. The *dose* is from eight to fifteen grains (0.5–1 Gm.).

Teucrium. *Teucrium Chamædrys* L. *Germander. Chamædrys. Petit Chêne*, Fr. *Edlar, Gamanderlein, Frauenbiss*, G.—A small European labiate, which has been employed as a mild corroborant in *uterine, rheumatic, gouty* and *scrofulous affections* and *intermittent fevers*. Germander was an ingredient in the *Portland powder*, noted as a remedy in gout. This powder, according to the original prescription, consisted of equal parts of the roots of *Aristolochia rotunda* L. and *Gentiana lutea* L. of the tops and leaves of *Teucrium Chamædrys* and *Erythræa Centaurium* (L.) Pers. and of the leaves of *Ajuga Chamæpitys* Schreb., or *ground pine*. The *dose* was a drachm every morning before breakfast for three months, then forty grains for three months, afterwards half a drachm for six months, and finally half a drachm every other day for a year. (Parr.)

Two other species of *Teucrium* have been used in medicine,—*T. Marum* L., *cat thyme*, or *Syrian herb mastich*, indigenous in the south of Europe, and *T. Scordium* L., or *water germander*, growing in the higher latitudes of the same continent. The former is a warm, stimulating, aromatic bitter, and has been recommended in *hysteria, amenorrhea* and *nervous debility;* the latter has the odor of garlic and a bitter, somewhat pungent taste, and was formerly highly esteemed as a corroborant in *low forms of disease;* but neither of them is now much employed. *T. Marum* is an errhine, and was formerly an ingredient of the *Pulvis Asari Compositus*.

A plant said to have been used advantageously in *cholera* in the Levant, a specimen of which was sent to Paris, proved to be *Teucrium Polium* L. (*J. P. C.*, xv, 352.) Moorhof (*Ph. Cent.*, 1893, 89) prepared a purified liquid extract from *T. Scordium*, and named it *teucrin*, which he recommends in the treatment of fungoid diseases and abscesses.

The *dose* of either of the three species is about half a drachm (2.0 Gm.).

Tfol is an argillaceous earth, containing free gelatinous silica, which is largely used in Northern Africa as a substitute for soap. It has been strongly recommended by Lahache for the purpose of emulsifying tar oil and for disinfecting purposes.

Thalictrum.—It appears probable that many species of this genus (Fam. *Ranunculaceæ*) have active medicinal or toxic properties. In 1879 Henriot and Doassans asserted that they had separated from the roots of the *Thalictrum macrocarpum* Gren., a shrub of the Pyrenees, a crystalline yellow substance, having very pronounced toxic principles, analogous to those of curare; and subsequently stated (*C. R. S. B.*, 1880) that this substance really consists of two principles,—an alkaloid, *thalictrine*, obtained in the form of prismatic needles, insoluble in water, soluble in alcohol, forming crystalline salts with acids, and *macrocarpin*, a yellow crystalline body, soluble in water, representing the coloring principle of thalictrum. Subsequently *berberine* was found by Doassans and Mousset in *Thalictrum flavum* L., *Fen Rue* or *Monk's Rhubarb*, a shrub widely distributed in Europe and Asia, macrocarpin being, according to this authority, very closely allied to berberine, but differing in that its color is not affected by ammonia. Rochebrune (*Toxicolog. Africaine*, i) has found both thalictrine and macrocarpin in the roots of *Thalictrum glaucum* Desf., of Spain. Thalictrine he states to be a very active cardiac poison, producing loss of power, convulsive movements, irregularity and depression of the heart's beat, and finally death in some cases in convulsions. According to Rochebrune, thalictrine also exists in the African species *Thalictrum rhynchocarpum* Q. Dillon and A. Rich.

Thalline. *Tetrahydroparaquinanisol* or *Tetrahydroparamethyloxyquinoline.* $C_9H_6H_4N(OCH_3)$.—The term *anisol* is applied to the methyl ether of phenol, and it is therefore methyloxybenzene. Skraup's synthesis of quinoline, C_9H_7N, was effected by heating aniline or amidobenzene with nitrobenzene, glycerin and sulphuric acid. By taking instead paramidoanisol, paranitroanisol, glycerin and sulphuric acid, Skraup obtained paraquinanisol, $C_9H_6N(OCH_3)$. This is then treated with tin and hydrochloric acid, when it takes up four atoms of hydrogen and becomes $C_9H_6H_4N(OCH_3)$. The name *thalline* was given to this base because of the deep green color produced by ferric chloride and other oxidizing agents. The base thalline is obtained in well-formed rhombic crystals, which fuse at 40° C. (104° F.) and recrystallize on cooling. It shows a neutral reaction and has a characteristic aromatic odor resembling that of coumarin. It is soluble in water, alcohol, and ether.

Thalline sulphate is a white crystalline powder which loses its two molecules of water of crystallization at 100° C. (212° F.) and melts at 110° C. (230° F.). It is soluble in five times its

weight of cold water and freely soluble in boiling water, soluble in 100 parts of alcohol. Both solutions turn brownish on exposure to air and light. The odor of the sulphate recalls that of anisol. *Thalline tartrate* is a white crystalline powder, fusing at 155° C. (311° F.) and possessing a coumarin-like odor. It is soluble in ten parts of water and hardly soluble in alcohol. Its aqueous solution has an acid reaction.

Thalline tartrate and sulphate are medicinally equivalent. They are powerful antipyretics, acting also, when in sufficient dose, as depressants both upon the vasomotor system and upon the heart, and, according to A. Robin, checking tissue waste in the body and having a very marked tendency to attack the red blood corpuscles. These salts have been used in practical medicine, in *doses* of from four to eight grains (0.26–0.5 Gm.), but are so prone to produce disagreeable symptoms, such as marked cyanosis, vomiting, diarrhea, albuminuria, etc., that their employment has been abandoned. According to Kreis, in from 4 to 4½ per cent. solution they are active germicides, and the frequent use of urethral injections of the 1 to 2 per cent. solution has been found very useful in *chronic gonorrhea*. Moncorvo states that thalline is an active hemostatic.

Thalline Periodide. *Thalline Periodosulphate.*—An iodine addition product of thalline sulphate. It occurs as black crystals soluble in alcohol. It has been used in the treatment of *carcinoma*, three to four grains (0.2–0.25 Gm.) being given in pill form every two or three hours. In cases where functional activity of the epidermal glands has ceased, pilocarpine in slight doses is given at the same time.

Thalline Salicylate. $C_{10}H_{13}NO.C_7H_6O_3$.—This occurs as a reddish, crystalline powder, soluble in alcohol and administered as an antiseptic and antipyretic in the treatment of *gonorrhea, typhoid fever*, etc. *Dose*, three to eight grains (0.2–0.5 Gm.).

Thallium. (Tl. Atomic weight, 204.0.)—This metal, discovered by spectrum analysis, has been found to prevail widely in nature. The credit of its discovery by Crookes in 1861 has been disputed by Lamy. Although the absorption of the salts of thallium appears to be slow they are certainly distributed everywhere, their presence having been recognized by Lamy by the green spectroscopic line in all the tissues of poisoned animals.

Thallium is an active poison, according to Swain and Bateman (*J. Bi. Chem.*, Jan., 1910), only slightly less toxic than arsenic. Moreover, it is distinctly accumulative in its effect, so that small doses repeated over periods of time may produce serious intoxication. The symptoms of acute poisoning in the lower animals by thallium are a disordered muscular action, as shown by tremors, inco-ordination, gradually increasing paralysis. Often, also, there is evidence of irritation of the intestinal tract, with vomiting and diarrhea. The pupils are dilated, there is salivation, conjunctivitis, with free mucous secretion, diuresis, embarrassment of respiration and more or less weakness of circulation. Death occurs in coma and is due to respiratory failure. After death there may be found some effusion of blood and inflammation of the lungs and intense congestion of the bowels, pericardial effusion and ecchymosis of the heart surface.

Cases of poisoning are uncommon in man, but Ballard (*Reports of the Boston City Hospital*, 1902) has recorded a case in which, after between two to four grains which were taken in the course of a week, there were produced diarrhea, muscular weakness and tenderness over the nerve trunks. As both lead and arsenic were found in the urine, however, it was doubtful how far the symptoms were due to the thallium. Olmer and Tian (*C. R. S. B.*, lxv, p. 742) report a case in which, after application of a paste of acetate of thallium to the chest, there were pains in the extremities, stomatitis, albuminuria and widespread alopecia. The loss of hair has been an almost constant symptom of human poisoning, and also occurs, according to Swain and Bateman, in the lower animals.

Sabouraud (*Revue Internationale de Medecin*, 1912) has recommended an ointment containing 1 per cent. of thallium acetate as a depilatory.

That thallium can produce widespread general neuritis is strongly indicated by the violent pains, especially of the legs, which have been noted by Lamy, by Combemale, and other observers, and also by the muscular atrophy which appears to be pronounced in chronic poisoning by the drug in the lower animals. Curci, indeed, claims that thallium is exclusively a muscle poison, and as long ago as 1874 Rabuteau recorded that after death from thallium the muscles did not respond to irritation. (See *Ed. M. J.*, 1874.)

Pozzi and Courtade assert that in some cases thallium causes swelling of the gums with a blue line at the junction with the teeth, but this symptom seems not to have been noticed by other observers. In 1898 Combemale claimed that in *doses* of one and a half grains (0.096 Gm.), given at bedtime, thallium acetate is a valuable remedy in the *colliquative sweats* of phthisis; that it is effective has been proved by Huchard and others; but in many cases it has produced severe peripheral pains, loss of hair, abdominal disturbance, and other very disagreeable symptoms.

Thanatol. *Guæthol. Ajacol. Pyro-catechin-mono-ethyl-ester.* $C_6H.OC_2H_5.OH$.—This is an oily liquid, homologous with guaiacol and having similar medicinal properties. (See p. 1415.)

Thapsia. *T. garganica* L. *Thapsie, Faux Fenouil*, Fr.—An umbelliferous plant, growing in Southeastern Europe, and well known to the ancients, named from the isle of Thapsos, where it was obtained. Theophrastus speaks of its root as emetic and purgative. After long neglect this plant has obtained a foothold in the French Codex, which recognizes a *Resina Thapsiæ* prepared by exhausting the bark of the root with alcohol and evaporating to a soft extract. From this extract the Codex further directs that an *Emplastrum Thapsiæ* shall be so prepared as to contain 7 per cent. of the resin combined with yellow wax, turpentine and colophony. The bark of the root and the resin are both objects of commerce. The bark is described by Stanislaus Martin as almost always doubly quilled, unless where altogether in small fragments, exteriorly rugose with the epidermis here and there detached in patches larger or smaller, and of a deep brown color, interiorly smooth and whitish and of a fibrous fracture. The size of the pieces varies, the largest not exceeding 6 dm. in length and 2.5 in width. It is said that great care is necessary, in removing the root from the bales, not to be injured by the powder which escapes, and which causes itching and swelling of the face and hands. By submitting *thapsia* to the successive action of alcohol and ether Pressoir obtained two resins. (*J. P. C.*, 4e sér., xi, 328.) Canzoneri finds that

the ethereal extract is an amber-colored syrupy resin possessing vesicating properties. From it he has obtained two acids, *octoic* or *caprylic* acid, and *thapsic* acid, besides a neutral non-nitrogenous vesicating substance. (See *A. J. P.*, vol. xiv, 325.) Cazenave objects to the plaster prepared from the resin and kept in masses, as it deteriorates by time. He proposes the following method of preparing a plaster extemporaneously when wanted. Dissolve the resin in alcohol and with the aid of a brush spread it on a suitable recipient, which may be of ordinary plaster, waxed taffetas, or simply gummed paper. A single layer is sufficient for the purpose of an active revulsion, but the effect may be increased at pleasure by increasing the number of layers. (*J. P. C.*, 1868, 29.) The French thapsia plaster is an exceedingly active counter-irritant, producing much inflammation of the skin with an eczematous eruption and intolerable itching and, if the application be maintained, finally an ulcerated and suppurated surface, which on healing leaves behind it pronounced scars. The therapeutic action of the plaster is that of a severe counter-irritant.

The resin from the root of *Thapsia Sylphium* St.-Laz., an Algerian plant, which most botanists believe to be a simple variety of *T. Garganica* L. is, according to Herlaut, more active than that of the official plant. (*Proc. A. Ph. A.*, xxvi, 250.) Heckel and Schlagdenhauffen (*N. R.*, June and July, 1887) find in the root of *Thapsia villosa* L. a vesicant resin, which acts more slowly and gently than does that of *T. Garganica*.

Theobromine Preparations.—The alkaloid *theobromine* (see p. 1122), which is itself insoluble in water, unites with several of the earthy metals to form soluble compounds. Advantage of this fact has been taken by manufacturers to place upon the market a large number of soluble preparations of theobromine. The majority of these preparations have the same range of therapeutic usefulness as the official theobromine and sodium salicylate.

Theobromine Acetyl-salicylate. $C_7H_8N_4O_2$. $C_9H_8O_4$.—A white crystalline powder, soluble in alcohol and insoluble in water. It has been stated that this combination of theobromine shows better results as a rapid acting diuretic than the other salts of the same base. *Dose*, five to fifteen grains (0.33–1.0 Gm.).

Theobromine Barium and Sodium Salicylate. Barutin.—This is a white, amorphous powder with a sweetish alkaline taste and soluble in about twenty parts of water. It represents about 25 per cent. of theobromine and 17 per cent. of barium. Carbonic acid causes a precipitation. *Dose*, three to eight grains (0.2–0.5 Gm.), which should be given well diluted.

Theobromine Lithium. Theobromose. $C_7H_7O_2N_4Li$.—It occurs as fine needle-like crystals, which are soluble in about one-half their weight of water. The solution is readily decomposed by atmospheric carbonic acid. It is used as a diuretic.

Theobromine and Lithium Benzoate. N. N. R. 1917. *Uropherin B.* $LiC_7H_7O_2N_4 + LiC_7H_5O_2$.—A white powder, soluble in five parts of water, representing 47 per cent. of theobromine. Precipitated by carbonic acid. Is stated to be more actively diuretic than other salts of theobromine. *Dose*, five to fifteen grains (0.3–1 Gm.).

Theobromine and Lithium Salicylate. N. N. R. 1914. *Uropherin S.* $LiC_7H_7O_2N_4 + LiC_7H_5O_3$.—Properties and uses the same as those of *Uropherin B.*, but it is somewhat more prone to disturb the stomach.

Theobromine and Sodium Acetate. N. N. R. 1917. *Aguirin. Theonacet.* $C_7H_7O_2N_4Na + NaC_2H_3O_2$.—A white, hydroscopic, alkaline powder, representing 60 per cent. of theobromine, readily soluble in water, forming a strongly alkaline solution which is incompatible with most inorganic salts, causes precipitation of alkaloid from solutions of their salt, darkens calomel, reduces potassium permanganate solution and is precipitated by carbon dioxide. The dry substance becomes pasty when triturated with chloral hydrate, phenol or piperazin. It is incompatible with carbonated beverages, acids, saccharin and mucilaginous liquids, alkaloids and alkaloidal reagents generally. Used as a diuretic. *Dose*, five to fifteen grains (0.3–1 Gm.) in solution.

Theobromine Salicylate. $C_7H_8O_2N_4.C_7H_6O_3$.—This forms fine white needle-like crystals of a bitter taste, acid in reaction and fairly soluble in water. *Dose*, five to fifteen grains (0.3–1 Gm.).

Theobromine and Sodium Benzoate.—A white soluble powder, representing 47 per cent. of theobromine. *Dose*, eight to fifteen grains (0.5–1.0 Gm.).

Theobromine and Sodium Citrate. Urocitral.—A white, alkaline powder, moderately soluble in water, representing 45 per cent. of theobromine. *Dose*, eight to fifteen grains (0.5–1.0 Gm.) several times a day.

Theobromine Sodium Formate. Thephorin. N. N. R. 1917. $NaC_7H_7O_2N_4 + NaCHO_2 + H_2O$.—A white, alkaline, bitterish powder, soluble in 10 parts of water and representing 62.5 per cent. of theobromine. Used as a diuretic. It is asserted to be more irritant to the kidneys than other theobromine salts, and must be used with caution in *nephritis*. *Dose*, five to eight grains (0.3–0.5 Gm.).

Theobromine and Sodium Iodide. Sodium Iodotheobromate. Eustenin. $C_7H_7O_2N_4Na.NaI$.—This is a white, hygroscopic powder, freely soluble in water, but decomposed with precipitation by carbonic and other acids. It represents 51 per cent. of theobromine and 42.6 per cent. of sodium iodide. It is believed to combine the therapeutic effects of these two drugs and is recommended especially as an anti-sclerotic in arterial degenerations, *angina pectoris, chronic nephritis* and similar conditions. The *dose* is eight to fifteen grains (0.5–1.0 Gm.) several times a day.

Theobromine Sodium Iodo-salicylate. Iodotheobromine.—This ambitious powder attempts to combine the actions of theobromine, the iodides and the salicylates. It occurs as a white powder, which is soluble in hot water. It has been recommended chiefly in aortic insufficiency. *Dose*, five to eight grains (0.3–0.5 Gm.).

Theobromine and Sodium Lactate.—A white hygroscopic alkaline powder, soluble in sixteen parts of water, readily decomposed by atmospheric carbonic acid.

Theobromine and Sodium Sulphate.—A white powder soluble in water and containing about 50 per cent. theobromine. It is used like other theobromine salts.

Theoform (not to be confounded with *thioform*).—This is a proprietary name of a condensation product of theobromine and formaldehyde with the addition of citric acid as a preservative. It occurs as a white, bitter powder representing 4 per cent. of theobromine and is soluble in water. *Dose*, fifteen grains (1 Gm.).

Theophylline Compounds.—Although theophylline is now official, it is more frequently employed in the form of one of its soluble compounds. The following are upon the market:

Theophylline Ethylene Diamine. Euphyllin.—This is a white crystalline substance, freely soluble in water and representing 78 per cent. of theophylline. The *dose* recommended is from one and a half to three grains (0.1–0.2 Gm.).

Theophylline Sodium Acetate. Acet-theocin Sodium. N. N. R. 1917. $NaC_7H_7O_2N_4 + NaC_2H_3O_2 + H_2O$.—This is a white, crystalline powder, representing approximately 60 per cent. of theocin, soluble in twenty parts of water. It is used as a diuretic in *doses* of three to five grains (0.2–0.3 Gm.) several times a day.

Theophylline Sodium Salicylate. $C_7H_7O_2N_4Na.C_6H_4.OH.COONa$.—This is soluble in fourteen parts of water. Its doses and uses are the same as the preceding.

Theophylline Sodium Formate. N. N. R. 1917. *Thephorin.* $C_7H_7O_2N_4Na.HCOONa + H_2O$.—This occurs as a white powder soluble in water and possessing valuable diuretic properties. *Dose*, eight to fifteen grains (0.5–1 Gm.).

Thermifugin. *Sodium-methyltrihydroxyquinoline Carbonate.* $C_9H_3(CH_3).NCOONa$.—A water-soluble powder of a white or a yellowish-white color. It is used as an analgesic and antipyretic in four grain (0.26 Gm.) *doses*.

Thermin. *Tetrahydro-β-naphthylamine Hydrochloride.* $C_{10}H_7.H_4.NH_2.HCl$.—The tetrahydro addition compound is formed when metallic sodium is caused to act upon naphthylamine in boiling amyl alcohol solution. It is a colorless to reddish-white crystalline powder, soluble in water, alcohol and amylic alcohol. The hydrochloride has been brought forward by Filehne of Breslau, as a local mydriatic of extraordinary power.

Jonescu (*A. E. P. P.*, 1909, lx, p. 345) has shown that tetra-hydronaphthylamin causes dilatation of the pupil by stimulating the sympathetic nerves and that the dilatation follows either the local installation or the subcutaneous injection of the drug; that it causes marked constriction of the blood vessels, chiefly by acting upon the vasomotor centers, although he believes the peripheral nerves to the vessels are also affected. The rise in temperature which it causes he attributes to a direct action upon the heat centers. According to Feri (*A. I. P. T.*, 1911, xxi, p. 27) there is in poisoning by *thermin* an increase in heat production with lessened heat dissipation which differentiates at once the fever it produces from that seen, for example, in infectious diseases. According to Sacharoff (*Z. E. P. T.*, vii, p. 225) the spasm of the blood vessels of the skin is in part responsible for this rise of temperature by preventing the dissipation of the excessive caloric. Thermin appears to cause a non-maximum dilation of the pupil and does not destroy the light reflexes. It is used as a mydriatic in strengths of from 1 to 5 per cent.

Thermodin. *N. N. R.* 1917. *Acetyl para-ethoxy-phenyl-urethane.* $C_6H_4(OC_2H_5)N(COCH_3)COOC_2H_5$.—A derivative of urethane in the form of a colorless, crystalline powder, fusing at from 86° to 88° C. (186.8°–190.4° F.), insoluble in water. It is used as an antipyretic in *doses* of from five to fifteen grains (0.32–1.0 Gm.).

Thermol. *Acetyl-salicyl-phenetidin. A-s-phen.* $C_{17}H_{17}NO_4$.—This substance is a white, crystalline, odorless, tasteless powder, which is claimed to be a harmless and active antipyretic and analgesic and as such has been used to a considerable extent in *typhoid fever, neuralgia, dysmenorrhea, migraine*, etc.; also as an antispasmodic in *whooping cough*. *Dose*, three to fifteen grains (0.2–1.0 Gm.).

Thevetia. *Yccotli.*—Inhabiting the damp, hot valleys of the Mexican Cordilleras is a large tree belonging to the *Apocynaceæ*, whose fruits are known by the natives as *huesos ó codos de fraile*, or *friar's elbow bones*, and are used as a topical application in *hemorrhoids*. The tree is the *Thevetia Jccotli* A. DC. In the seeds Herrera found a glucoside, *thevetin*. (*A. J. P.*, 1877, 145.) Closely allied to *T. Yccotli* is *T. nereifolia* Juss., a tree which probably grows also in Mexico, but has been found by botanists chiefly, if not solely, in the West Indian Islands, Colombia, Peru and other parts of South America. De Vrij very many years ago discovered in its seeds a glucoside which was closely studied by Blas. (*Neues Jahrb. f. Pharmacie*, Bd. xxxiv, 1854, 1.) He gave it the name of *thevetin* and the formula $C_{54}H_{84}O_{24}$ and believed it to be identical with *cerberin*, previously found by Oudemann in *Cerbera Odallam* Ham., also an apocynaceous plant, but Plugge (*A Pharm.*, 1893, 10) after a thorough study found that cerberin was not identical with either tanghinin or thevetin. With the former it is isomeric, showing the same percentage composition, but has different crystalline form and melting point—cerberin 192° C. (377.6° F.), tanghinin 182° C. (359.6° F.). From thevetin it differs not only in composition, but in the nature of the decomposition products. Cerberin, $C_{27}H_{40}O_8$, is decomposed into *cerberetin*, $C_{19}H_{26}O_4$, a citron-yellow amorphous powder melting at 85.5° C. (186° F.), and glucose, while thevetin, $C_{54}H_{84}O_{24}$, is split into *theveresin*, $C_{48}H_{70}O_{17}$, a white powder, and glucose.

Merck (*Jahresb. für*, 1892, 57) described a glucoside *cerberin* to which he gives the formula $C_{25}H_{38}O_{12}$, which name he changed to *cerberid* in 1911. He states that it was obtained from a Mexican plant, probably *Thevetia Yccotli*. Whether this glucoside is identical with the thevetin of Blas cannot be definitely stated. Blas found that the thevetin of De Vrij boiled in diluted sulphuric acid splits into glucose and *theveresin*, which has the formula $C_{48}H_{70}O_{17}$. Thevetin occurs in minute crystals, odorless, of a bitter taste, slightly soluble in cold water (twelve parts), freely so in boiling water, diluted and strong alcohol, acetic acid, insoluble in ether. Its most characteristic reaction appears to be its dissolving in concentrated sulphuric acid, with the production of a reddish-brown color, changing to a cherry-red, and after some hours to a violet color. In commerce it occurs as a yellowish-white, amorphous bitter powder, easily soluble in water and alcohol. Theveresin is only slightly soluble in boiling water. These substances are active poisons. *Thevetosin*, a crystalline glucoside, was made by Herrera from the seeds of *T. Yccotli*. It is a cardiac poison. (*M. R.*, 1911.) A number of cases of poisoning by the seeds of the East Indian thevetia has occurred; the symptoms have been repeated vomiting, a slow, very feeble pulse, delirium, convulsive movements and coma. The physiological action of the thevetin from *T. nereifolia* has been investigated chiefly by König. (*A. E. P. P.*, Bd. v, 228.)

David Cerna finds that the glucoside of *T. Yccotli* (*P. M. T.*, ix, 396) with sulphuric acid

affords a clear greenish-yellow solution gradually passing to brown and brownish-violet and finally becoming a permanent cherry-brown color, which changes on the addition of potassium bicarbonate to an emerald-green; also that it is in moderate doses stimulant both to the circulation and respiration, but finally paralyzes the heart muscle and the respiratory apparatus; that it causes cerebral convulsions and spinal paralysis, abolishing sensation and reflex activity before voluntary movement by an influence upon the sensory nerves or spinal tract. Zotos N. Zotos (*In. Dis.*, Dorpat, 1892) states that *cerberin* belongs physiologically to the digitalin group.

Thialdine. $C_6H_{13}NS_2$.—This substance, obtained when hydrogen sulphide acts upon aldehyde-ammonia in aqueous solution, forms crystals melting at 43° C. (109.4° F.), which are but slightly soluble in water, more easily in alcohol. It has been investigated by Lusini, who found it a general paralyzing agent, acting powerfully upon the heart, which it arrests in diastole; while *carbothialdine*, $C_5H_{10}N_2S_2$, formed by the action of carbon disulphide in alcoholic solution upon aldehyde-ammonia, acts as a tetanizing agent and does not affect the heart. (See *Nouv. Rem.*, Nov., 1890.)

Thigenol. *N. N. R.* 1917.—This proposed substitute for ichthyol is said to be the sodium salt of a sulphonic acid of a synthetic sulphur oil, and has been used in 20 per cent. ointment for the treatment of *dermatitis, prurigo* and other diseases of the skin. (*K. T. W.*, 1902, No. 6.)

Thilanin.—This substance is said to be made by the action of sulphur upon lanolin. It is of the consistence of lanolin, of a brownish color and peculiar odor. It is said not to be irritating, and has been used without dilution with asserted excellent results in *chronic eczema* and other *skin eruptions* in which uncombined sulphur has been employed.

Thilaven. *Thiozine.* $C_5H_7S_3C_2CH_2C_5H_9O_2$.—This is a solution of linalyl-acet-thiozone in alkaline theozone. It occurs as a dark brown fluid with an alkaline reaction and a pleasant lavender-like odor. It contains 5 per cent. of sulphur, of which it is claimed about one-sixth is in a form readily absorbable through the skin. It has been used for similar purposes to ichthyol by Knorr (*Med. Klin.*, 1910) with satisfactory results.

Thiocol. *N. N. R.* 1917. *Potassium Guaiacol Sulphonate. Orthocoll.* $C_6H_3.(OCH_3)OH.SO_3K$.—This is a fine white powder, having a taste at first bitter and afterwards sweetish; readily soluble in water, sparingly so in alcohol; containing about 60 per cent. of guaiacol. It is pleasant to the taste and not irritant to the gastric or other mucous membranes. Its freedom from odor, ready absorption and non-irritant action on the mucous membrane are among its recommendations that have been reported by its introducers. The original commendation of it by C. Schwartz (*K. T. W.*, 1898), in *tuberculosis, chronic bronchitis* and *intestinal catarrh*, has been confirmed by various clinicians. Cole (*Practitioner*, November, 1911) finds its effects about the same as those of creosote, over which it has the great advantage of being practically tasteless and much less likely to irritate the stomach. It occasionally produces a rash which, however, disappears quickly when the remedy is stopped. The *dose* is eight to twenty grains (0.5–1.2 Gm.).

Thioform. *Basic Bismuth Dithiosalicylate.* $2(S.C_6H_3[OH]COOBiO) + Bi_2O_3 + 2H_2O$ (not to be confounded with theoform).—A yellowish-brown powder containing 72 per cent. bismuth oxide. It is used as an antiseptic dusting powder in *eczema, erysipelas, psoriasis*, etc.

Thiol. *N. N. R.* 1917.—This is a thin, dark brown, neutral liquid, with an odor somewhat like that of Russia leather, having a specific gravity of from 1.082 to 1.089; its aqueous solution is transparent, froths when shaken, and is not precipitated by strong alcohol; it is also feebly soluble in glycerin. On evaporation, liquid thiol yields about 40 per cent. of dried thiol. It is prepared from paraffin oils of from 0.89 to 0.90 sp. gr., which are treated with sulphur at high temperatures. The unsaturated hydrocarbons (olefins, etc.) are alone attacked, and these are then extracted by suitable solvents from the saturated hydrocarbons. They are then acted upon by concentrated sulphuric acid at low temperatures, and the thiol separated out by the addition of ice. It may then be evaporated *in vacuo* to either *thiolum liquidum* or *.thiolum siccum.*

It is asserted that thiol possesses the remedial properties of ichthyol, to which it is superior on account of its being odorless. It has been used in the treatment of superficial and deep inflammations, as in *eczema* and *syphilitic ulcers* and in various joint conditions as *sprains, rheumatism* and the like. Kretzomer states that painted along the nerve in cases of *acute sciatica*, it produces immediate relief. (*All. M. C. Z.*, 1909.)

The liquid is used in the form of a solution or ointment; the dried thiol is sometimes employed as a powder. In *rheumatism* thiol has been given internally in *doses* of from five to ten minims (0.3–0.6 mil), or the dried preparation in *doses* of from one to two grains (0.065–0.13 Gm.).

Thiolinic Acid.—This is a darkish-green extract-like mass, having the odor of mustard, which has been called *sulphurated linseed oil.* It is insoluble in water; soluble in alcohol. Its alkaline combinations, especially with the sodium salts, have been recommended as substitutes for thiol and ichthyol.

Thionine. *Lauth's Violet.*—The oxidation product of *imidamidoiodiphenylimide*, $C_{12}H_{10}N_3SCl$. A greenish-black powder, having a metallic luster. It dissolves easily in water, imparting to the solution an intense violet color. It is used as a microscopic stain for nuclei and also in metachromatic investigations (for mast cells, mucus, etc.).

Thiophene (C_4H_4S) was recognized by Victor Meyer in 1883 as being an invariable accompaniment of benzene as produced from coal tar, and because of the similarity of properties, adhering very closely to it through all reactions. It can be separated by shaking the benzene with one-tenth of its bulk of concentrated sulphuric acid until the addition of a little isatine no longer produces a blue color (indophenin reaction). Steinkopf obtained a 40 per cent. yield of *thiophene* by passing acetylene over pyrites heated to 300° C. (572° F.). (*Chem. Trade Jour.*, 1911, 394.) Thiophene is a colorless, mobile oil, of faint odor, and boils at 84° C. (183.2° F.). Just as benzene is accompanied in coal tar by toluene, xylene and higher homologues, so thiophene is accompanied by *thiotolene* (*methyl-thiophene*), $C_4H_3S.CH_3$ and *thioxene* (*dimethyl-thiophene*), $C_4H_2S.(CH_3)_2$. Thiophene and its homologues yield a large number of brilliant dye colors analogous to those derived from benzene. It was

first physiologically tested by A. Heffter (*A. G. P.*, 39, 420), who found that it appeared in the urine, and lessened the elimination of sulphuric acid in the urine. E. Spiegler (*Th. M.*, Feb., 1892) has employed in *skin diseases*—1, *Sodium thiophene sulphonate*, $C_4H_3S—NaSO_3$; 2, *Thiophenediiodide*, $C_4H_2I_2S$. The first of these compounds is a white crystalline powder, containing 33 per cent. of sulphur, having a feeble, disagreeable odor. It was found in the form of an ointment to act very well in *prurigo* with *eczema*. Thiophenediiodide occurs in tabular crystals, melting at 40.5° C. (105° F.), having a characteristic, not disagreeable odor, insoluble in water, but very feebly soluble in ether, chloroform and warm alcohol, soluble with difficulty in cold alcohol; containing 75.5 per cent. of iodine and 9.5 per cent. of sulphur. It was found to be antiseptic and is one of the compounds suggested as a substitute for iodoform. The *tetrabromide of thiophene*, C_4Br_4S, obtained by the complete bromination of theophene, is recommended as an antiseptic. It occurs as a yellow crystalline powder soluble in alcohol.

Thioresorcin. $C_6H_4(OS)_2$.—A yellowish-gray powder, insoluble in water, made by fusing together one molecule of resorcinol and two molecules of sulphur. It has been recommended as a substitute for iodoform, but has given rise to unpleasant symptoms.

Thiosinamine. *N. N. R.* 1917. *Rhodallin Allylthio-urea. Allylsulpho-urea. Allylsulphocarbamide.* $(NH_2).CS.NHCH_2.CH : CH_2$.—This occurs in colorless, monoclinic or rhombic crystals, of a bitter taste and feeble garlic-like odor. It is moderately soluble in water, very soluble in alcohol and ether. It possesses no bactericidal properties.

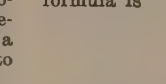
Under the name of *Fibrolysin* a 15 per cent. solution of the double salts of *thiosinamine* and *sodium salicylate* is marketed in the form of ampuls, containing 2.3 mils of the solution. This solution decomposes rapidly on exposure to the air.

Thiosinamine was introduced into medicine by Von Hebra (*Internat. Klin. Rundschau*, September, 1905) in the treatment of various conditions accompanied with formation of fibrous tissue. He states that after its injection there is a temporary reduction in the number of leukocytes, followed by pronounced hyper-leukocytosis which persists for a considerable period of time. The occurrence of leukocytosis has been pretty generally confirmed by a number of authorities, some of whom have attributed the beneficial effects of the drug to this action. Starkenstein, however (*Th. M.*, 1910), believes that it is due to a power of encouraging the hydrolysis of collagen into gelatin, thereby leading to the softening of the connective tissue. While there is some contradiction of opinion among those who have investigated the action of this drug clinically, there is considerable evidence that it is often a remedy of great service in aiding in the absorption of connective tissue. Among the conditions in which this remedy has received recommendation may be mentioned excessive scarring as from *burns*, *keloids*, *urethral* and *œsophageal strictures*, and various other forms of cicatricial formations. Besides these, asserted benefit has been reported in sclerotic conditions of the ear attended with *deafness*, and in sclerosis of the central nervous system as *locomotor ataxia*, and in *arterial fibrosis*. The remedy, whatever may be said of its efficacy, is not entirely invocuous. A number of instances of excessive reaction, attended with chills and sweating following by fever, have been reported, and Pritchard reports a case of *purpura hemorrhagica*, which ended fatally, following 18 injections.

Thiosinamine may be administered by the mouth, in *doses* of one-half to two grains (0.03–0.12 Gm.) several times a day; for hypodermic use it may be dissolved in alcohol or glycerin. Fibrolysin is marketed only in the form of hermetically sealed vials each of which represents five grains (0.2 Gm.) of thiosinamine. The contents of one of these vials may be injected at one *dose* daily, or on alternate days.

Iodolysin is a compound said to contain 43 per cent. of thiosinamine and 47 per cent. of iodine. The advantage is claimed over other preparations that it is non-irritant and is especially suitable for hypodermic injection. Whitehorn-Cole (*F. Th.*, 1910, p. 69) reports favorably upon its use in *rheumatic arthritis*. The *dose* is from five to eight grains (0.32–0.5 Gm.).

Thiosinamine-ethyl-iodide. *Tiodine.* $C_6H_{13}N_2SI$.—Under the name of *tiodine*, the compound resulting from heating thiosinamine with ethyl-iodide has been introduced into medicine. Its formula is



It forms colorless crystals readily soluble in water and alcohol. It has been used for the same class of cases as thiosinamine, especially, however, for the relief of lesions of the central nervous system. Its injection is stated to be painless. It may be administered either by mouth or hypodermically. The *dose* is from one and one-half to three grains (0.1–0.2 Gm.), if by the mouth several times a day, if hypodermically, every other day.

Thorium.—*Thorium dioxide* has been used as a substitute for bismuth subnitrate in making X-ray pictures of the alimentary tract. According to Kaestle (*M. M. W.*, 1908), it is absolutely inert physiologically, and is very opaque to the X-ray. S. Tracey has used the antiseptic action of a current of air passed over heated thorium oxide in the treatment of *tuberculosis* with apparently beneficial results.

Thorium Nitrate. $Th(NO_3)_4 + 4H_2O$.—It forms white, aggregate crystals which are very soluble in water. Depending on the fact or the belief that thorium salts are radio-active much attention has been called to this salt as being the most advantageous of the thorium salts for utilization. A solution of the nitrate has been employed in the treatment of parasitic skin diseases and a weak solution has been administered internally in the treatment of *rheumatism*.

Thiuret. $C_6H_7N_3S_2$.—A sulphurated compound made by the oxidation of *phenyl-dithiobiuret;* it is a bulky, inodorous, crystalline powder, insoluble in water, soluble in alcohol and ether, easily decomposed by alkaline solutions with liberation of sulphur. It is used as a substitute for iodoform.

Thuja. *N. F. IV. Arbor Vitæ. White Cedar.*—"The recently dried, leafy young twigs of *Thuja occidentalis* Linné (Fam. *Pinaceæ*), with stems not over 4 mm. in diameter, and without the presence of more than 1 per cent. of foreign substances." It is specifically characterized by the appressed-imbricated leaves, the pointless cone-scales, and the broad wings etxending all around the seeds. It attains a height of 20 m., and grows in swampy grounds from Pennsylvania northward and west-

ward, often forming extensive "cedar swamps." In Canada and the extreme northern parts of the United States it is commonly called *white cedar*, a name sometimes applied to *Chamæcyparis thyoides* (L.) B. S. P., which latter is more properly called *Southern white cedar*. The wood is reddish, soft, fine-grained, and very durable. The leaves, or small twigs invested with the leaves, have an agreeable, balsamic odor, specially when rubbed, and a strong, balsamic, camphoraceous, bitter taste. The twigs are described as "fan-shaped, flattened, bearing the scale-like leaves appressed in four rows; leaves of the edges boat-shaped, the intermediate flat, those at the tips of the twigs very broad, the lower elongated, all bearing conspicuous glands on the back. Odor strongly balsamic, aromatic and pungent; taste camphoraceous, terebinthinate and bitter. Thuja yields not more than 7 per cent. of ash." *N. F.* A. Kawalier, of Vienna, found in them volatile oil, a bitter principle called *pinipicrin*, $C_{22}H_{36}O_{11}$, which occurs also in *Pinus sylvestris*, sugar, gelatinous matter, a variety of wax, resin, and tannic acid; also a peculiar crystallizable coloring principle, *thujin*, to which he gives the formula $C_{20}H_{22}O_{12}$. It is of a citron-yellow color and an astringent taste, soluble in alcohol, inflammable, and when its alcoholic solution is heated with diluted hydrochloric or sulphuric acid it splits up into glucose and *thujigenin*,

$$C_{20}H_{22}O_{12} + H_2O = C_6H_{12}O_6 + C_{14}H_{12}O_7$$

and by continuing the reaction another molecule of water is taken up by the latter and *thujetin*, $C_{14}H_{14}O_8$, is formed. Thujetin is possibly identical with quercetin. When thujin is heated with barium hydroxide, instead of thujetin is obtained another product, *thujetic acid*, $C_{28}H_{22}O_{13}$. The same chemist determined that the tannic acid of this plant is identical with *pinitannic acid*, which he had previously obtained from the leaves of *Pinus sylvestris* L. (See, for details, *Chem. Gaz.*, Nos. 392, 393, 1859.) According to Hübschmann, the leaves and twigs of *Thuja occidentalis* yield also 1 per cent. of an essential oil of sharp, camphor-like taste, sp. gr. 0.925, boiling point from 190° to 206° C. (374°–402.8° F.), and easily soluble in alcohol. According to *Schim. Rep.*, April, 1897, thuja oil (*oil of white cedar*) contains pinene, fenchone, thujone, and probably carvone.

F. K. Bailey has reported a case of poisoning in a girl, aged fifteen, who took sixteen drops of the oil of white cedar, and directly afterwards fell unconscious, with clonic spasms followed by epileptiform convulsions lasting at intervals for several hours. Long-continued irritation of the stomach resulted. (*N. R.*, 1872.)

In the form of decoction, thuja has been used in *intermittent fever*, and, according to Schoepf, in *coughs*, *fevers*, *scurvy*, and *rheumatism*, and as an emmenagogue. Made into an ointment with lard or other animal fat, the leaves are said to form a useful local application in rheumatic complaints. Sicard and Larue (*Gaz. des. Hôp.*, 1909) assert that the injection of the tincture of thuja into warts will cause their rapid disappearance. A yellowish-green volatile oil, which may be obtained from the leaves by distillation, has been used with success in *worms*. According to Hildebrand both fenchone and thujone act as stimulants to the heart muscle. (*A. E. P. P.*, xlviii.) According to Prochnow (*A. I. P. T.*, xxi, p. 314) the infusion of thuja has a stimulating effect upon the isolated uterus similar to that of hydrastis. The *dose* of the fluidextract made with alcohol is half a fluidrachm (2 mils) from three to six times a day.

Thymacetin. $C_6H_2(CH_3)C_3H_7\left\{\begin{matrix}OC_2H_5\\NH(C_2H_3O)\end{matrix}\right.$.—This is a white, crystalline powder, slightly soluble in water, having the same chemical relation to thymol that phenacetin has to phenol. According to Jolly (*Cb. G. T.*, Feb., 1892), it is a very valuable analgesic and hypnotic. *Dose*, from three to fifteen grains (0.2–1.0 Gm.), best given in capsules.

Thyme. *N. F. IV. Thymus. Common or Garden Thyme.*—"The dried tops of *Thymus vulgaris* Linne (Fam. *Labiatæ*), collected when the plant is in flower." *N. F.* It is extensively grown in the United States for flavoring purposes. It is also used to some extent in medicine. The N. F. description is as follows: "Stems quadrangular, about 0.5 mm. in diameter, grayish-brown or purplish in color, pubescent, nodes from 5 to 20 mm. apart, occasionally with the opposite leaves attached; leaves linear, linear-lanceolate, or ovate-oblong, from 0.5 to 4 mm. in length and from 0.5 to 2 mm. in breadth, summit acute, base obtuse tapering into a petiole from 0.5 to 2 mm. in length, margin revolute, upper surface grayish-green, puberulent, with numerous one-celled, thick-walled, non-glandular hairs; lower surface grayish, pubescent, with non-glandular, one- to four-celled, thick-walled, rough simple hairs, up to 0.135 mm. in length and usually curved at the first joint in the bases; numerous compound glandular secreting hairs, with short one-celled stalk occurring chiefly on the upper surface and depressed in the cuticle, which give the leaf a glandular-punctate appearance; inflorescence in about twelve-flowered axillary whorls; flowers polygamous, calyx tubular, about 4 mm. in length, ovoid or slightly curved on the lower side near the base, from nine- to twelve-nerved, pubescent, the throat bearded with longitudinally striated, straight simple hairs up to 1 mm. in length, bilabiate, upper lip three-toothed, lower lip with two hairy, ascending, attenuate divisions, corolla about twice as long as the calyx, purplish, smooth within, slightly pubescent without, upper lip emarginate, lower spreading and three-lobed, stamens slightly didynamous and exserted, stigma bifid; nutlets about 0.5 mm. in diameter, spheroidal and finely tuberculate. Odor agreeable, aromatic; taste aromatic and warming. Thyme yields not more than 14 per cent. of ash." *N. F.*

Thyme owes its therapeutic virtues to its volatile oil. (See *Oleum Thymi*, PART I). It is occasionally used in domestic medicine, like other aromatic plants, in the form of a hot infusion as a diaphoretic. *Fluidextract of Thyme N F. IV* is made with a menstruum of 10 volumes of glycerin, 25 volumes of alcohol and 65 volumes of water followed by 1 volume of alcohol and 3 volumes of water. The *dose* is one fluidrachm (4 mils).

Thymidol. *Methyl-propyl-phenol-menthol.*—This is stated to be a condensation product of thymol and menthol. It is used in preparing antiseptic washes for the mouth and nose, and also for filling tooth cavities.

Thymoform. *Thymoloform.* $CH_2:(C_6H_3[CH_3][C_3H_7]O)_2$.—It is made by heating 100 parts of thymol with 100 parts of a 40 per cent. solution of formaldehyde and gradually stirring in 100 parts of concentrated hydrochloric acid. It is in the form of a yellowish, tasteless powder, having a faint odor of thymol. It is readily soluble in alcohol, ether, chloroform and olive oil, but insoluble

in water, petroleum, benzin, and glycerin. It is used as an antiseptic dusting powder.

Thymol Carbonate. *Thymol Urethane. Thymolcarbonic Ether. Thymotal. Tyratol.* CO $(NH_2)O.C_{10}H_{13}$.—J. F. Pohl, by the same process by which guaiacol is converted into guaiacol carbonate, has produced from thymol a nearly tasteless, colorless, crystalline compound of neutral reaction, fusing at 49° C. (120.2° F.). It is slightly soluble in water, but is decomposed by the alkaline juices of the intestine, thymol being liberated. It is claimed that this substance is as effective as thymol against the *anchylostoma*, and, owing to its not dissolving in the stomach, is much less apt to produce disagreeable symptoms. (*A. J. P.*, March, 1901, 143.) *Dose*, for adult, thirty grains (2 Gm.) three times a day for four days, followed by brisk purgation.

Thyresol. *N. N. R.* 1917. $C_{15}H_{23}O.CH_3$.—The *methyl ether of santalol* is an almost colorless fluid. Sp. gr. 0.93–0.94, boiling point 149°–156° C. (287.6°–312.8° F.) at 16 mm. pressure. The preparation is practically insoluble in water, but dissolves to a clear fluid in all proportions in alcohol, ether, and oils. It has a slight sandal-wood odor. It has been used by Knauth (*D. M. W.*, 1909), and others, as a substitute for santalol in the treatment of *urethritis*. According to Knauth it is not split up in the organism but appears in the urine in combination with glycuronic acid.

Tilia. *Linden Tree.*—The dried flowers of *Tilia curopæa L.*, and of other species of *tilia* (Fam. *Tiliaceæ*), are official in the German Pharmacopœia under the head of *Flores Tiliæ*. The flowers are yellowish or greenish-white having 5 sepals and 5 petals. The 5 original stamens, by chorisis have each developed a cluster and at the base occurs in addition, a spatulate petal-like body opposite each of the petals. The pistil has a 5-locular ovary which is surmounted by a single style and a 5-toothed stigma. The flowers contain a colorless, fragrant, volatile oil. The bark has been said to contain a neutral body, *tiliadin*, and a glucoside, *tilicin*. (See *A. J. P.*, 1890; *P. J.*, 66, 105.) The infusion is used as a household remedy to relieve hysteria and indigestion.

Timbo.—This name is applied in Brazil to various sapindaceous plants, used as fish poisons. Among these is *Serjania curassavica*, Radlk. (*Paullinia pinnata* L.), in which Stanislaus Martin (*B. G. T.*, xcii) has found an alkaloid, *timbonine;* F. Pfaff have obtained from a *timbo* of unknown origin two alkaloids, *timboin* and *anhydrotimboin*, also an oily compound, *timbol*. (*A. J. P.*, Nov., 1891.)

Tin. (Sn. At. wt., 118.1.) *Stannum. Etain*, Fr. *Zinn*, G.—This was recognized in the old Edinburgh and Dublin Pharmacopœias, and in the U. S. of 1850, but is no longer official. It has, however, too long ranked among recognized remedies to be passed without notice. Tin is one of the metals which have been known from the earliest ages. It exists generally as an oxide (in *stone* and *wood tin*), rarely as a sulphide (*tin pyrites*), and is by no means generally diffused. It is found in England, Spain, Germany, Bohemia, and Hungary, in Europe, and sparingly in some parts of the United States; in the island of Banca and the Peninsula of Malacca in Asia; in Bolivia, and at Durango in Mexico. The mines of Banca furnish the purest tin. The metal is extracted from the native oxide. When this occurs in its purest state, in detached roundish grains, called *stream tin*, the reduction is effected by heating with charcoal. When the common oxide, called *mine tin*, is reduced, it requires to be freed, by pounding and washing, from the adhering gangue; after which it is roasted to drive off sulphur, arsenic, and antimony, and finally reduced in furnaces by means of stone coal. The metal, as thus obtained, is called *block tin*, and is not pure. The purest kind of tin known in commerce is called *grain tin*. The world's production of tin for 1915 was 112,281 tons, the largest producers being Malaga, Bolivia, and Banca in the order named.

Tin is a malleable, rather soft metal, of a silver-white color. It may be beaten out into thin leaves, called *tin foil*. It undergoes a superficial tarnish in the air. Its taste is slight, and when rubbed it exhales a peculiar odor. Its ductility, and tenacity are small; when bent to and fro, it emits a cracking noise, which is characteristic. Its sp. gr. is 7.29, melting point 235° C. (455° F.), and it volatilizes at a white heat. It forms two oxides. The *stannous oxide*, SnO is of a grayish-black color. When perfectly pure it has, according to Roth, a red color. *Stannic oxide*, SnO_2, or *dioxide*, froms two hydrates, both being acids—*stannic acid*, $SnO_2.H_2O$, and *metastannic acid*, $Sn_5O_{10}.5H_2O$, or $(H_2SnO_3)_5$.

The tin of commerce is often impure, being contaminated with other metals, introduced by fraud or present in consequence of the mode of extraction from the ore. A high specific gravity is an indication of impurity. When its color has a bluish or grayish cast, the presence of copper, lead, iron, or antimony may be suspected. Arsenic renders it whiter, but at the same time harder, and lead, copper, and iron cause it to become brittle. Pure tin is converted by nitric acid into a white powder (*metastannic acid*), without being dissolved. Boiled with hydrochloric acid, it forms a solution which yields a white precipitate with potassium ferrocyanide. A blue precipitate with this test indicates iron, a brown one copper, and a violet-blue one both iron and copper. If lead be present, a precipitate will be produced by magnesium sulphate. The Malacca and Banca tin and the English grain tin are the purest kinds found in commerce. Banca tin, from analyses by Mulder, appears to be particularly pure, containing only one twenty-fifth of one per cent. of foreign metals. Block tin and the metal obtained from Germany are usually of inferior quality.

Tin enters into the composition of bronze, bell metal, pewter, and plumber's solder. It is used also in making tin plate, which is sheet iron coated with tin, in making tin amalgam for silvering looking glasses, and in forming the *solution of stannous chloride* (*bichloride of tin*), a combination essential for the dyer's use. It is employed in fabricating various vessels and instruments useful in domestic economy and the arts. Being unaffected by weak acids, it forms a good material for vessels intended for boiling operations in pharmacy. A *false tin foil* is considerably used at present, made by coating lead with tin, and then rolling it out into thin sheets. As tin foil is employed for enclosing medicinal powders and perishable articles of food and medicine, care should be taken not to use this substituted preparation.

Powder of Tin. Stanni Pulvis.—For directions for making, see 16th edition, *U. S. D. Powder of tin* was used as a mechanical anthelmintic, but has very properly gone out of vogue. The *dose* is half an ounce, mixed with molasses, given for several successive mornings, and then followed by a brisk cathartic purge. In the *J. P. C.*, 4e sér., xix,

78, is reported a death believed to have been caused by tin. Pattengo (*A. E. P. P.*, xvii, 1886) confirms the old statement of Orfila that the metal is of no therapeutic value. Three-fourths of a grain of the chloride intravenously injected into a dog suffice to cause trembling, Cheyne-Stokes respiration, opisthotonos, and death. *Stannous chloride*, or *chloride of tin*, is a violent irritant and mild caustic. Chemically pure tin, given internally, is probably not absorbed. (See 16th edition, *U. S. D.*)

Tinospora. *Br. Add.* 1900.—"The dried stem of *Tinospora cordifolia* Miers (Fam. *Menispermaceæ*), collected in the hot season." *Br. Add.*, 1900. *Tinospora* has long been used in India as a medicine and in the preparation of a starch known as *gilæ-ka-sat* or as *palo*. It is said to be a tonic, antiperiodic, and a diuretic. Flückiger obtained from it traces of an alkaloid and a bitter glucoside. The Br. Add., 1900, recognized an *infusion* (*Infusum Tinosporæ* Br. Add., 1900, two ounces to the pint), *dose* one-half to one fluidounce (15–30 mils); a *tincture* (*Tinctura Tinosporæ* Br. Add., 1900, four ounces to the pint), *dose*, one-half to one fluidrachm (1.8–3.75 mils); and a *concentrated solution* (*Liquor Tinosporæ Concentratus* Br. Add., 1900), *dose*, one-half to one fluidrachm (1.8–3.75 mils). *Tinospora crispa* Miers, which is abundant in the Philippines, is used freely by the natives under the name of *makabuhay* (that is, "You may live"), as a panacea, especially valuable in *general debility*, in chronic *rheumatism*, and in *malarial fevers*. It may be prepared in the same way and given in the same doses as *Tinospora cordifolia*.

Tissa. *Tissa rubra* (L.) Brit. [now *Spergularia rubra* (L.) J. and C. Presl.], is a native of Malta, Sicily, and Algiers, and is found growing in dry, sandy soil from Quebec to Virginia. It has long been used as a popular remedy in diseases of the bladder. It was shown by F. Vigier (*J. P. C.*, 1879, ii, p. 371) to contain a resinous aromatic substance which is probably its active principle. It is strongly recommended by Bertherand in *calculous diseases* and acute and chronic *cystitis*. The aqueous extract may be given in *doses* of thirty grains (2.0 Gm.); or the fluidextract, *dose*, a fluidrachm (3.75 mils), three or four times a day.

Titanium. Ti = 48.1.—A hard, gray-colored metal in powdery fragments, specific gravity 3.589. It is soluble in warm hydrochloric acid. Pick (*Med. Klin.*, 1911) has used various salts of *titanium*, especially the sulphate and salicylate, with asserted benefit as local remedies in the treatment of *eczema*, *lupus*, *rhinitis* and *conjunctivitis*. On the skin he uses solutions of from one-quarter to one-half per cent. of titanium sulphate, which must be freshly made, as the salt is decomposed by water. For mucous membranes the solution may vary in strength from one-twentieth to one-tenth of one per cent.

Tobacco. *Tabacum. U. S.* 1890. *Nicotiana Tabacum* L.—The Virginia *tobacco* plant is an annual with a large, fibrous root, and an erect, round, hairy, viscid stem, which branches near the top, and rises from three to six feet in height. The leaves are numerous, alternate, sessile, and somewhat decurrent, very large, ovate-lanceolate, pointed, entire, slightly viscid, of a pale green color, and have a narcotic odor. The seeds, examined by F. M. Brandt, yielded no narcotic principle, though a protein-like substance contained in them was thought by its decomposition to produce nicotine. (*Neues, Jahrb. für Pharm.*, xxi, 42.) William Procter also failed to find nicotine in the seeds. (*Proc. A. Ph. A.*, 1858, 296.)

There is good reason to believe that this plant is a native of tropical America, where it was found by the Spaniards upon their arrival. It is at present cultivated in most parts of the world, and nowhere more abundantly than within the limits of the United States. Virginia is, perhaps, the region most celebrated for its culture. The young shoots, produced from seeds thickly sown in beds, are transplanted into the fields during the month of May, and set in rows with an interval of three or four feet between the plants. Through the whole period of its growth the crop requires constant attention. The development of the leaves is promoted by removing the top of each plant and thus preventing it from running into flower and seed. The harvest is in August. The ripe plants, having been cut off above their roots, are dried under cover, and then stripped of their leaves, which are tied in bundles and packed in hogsheads. While hung up in the drying houses, they undergo a curing process, consisting in exposure to a considerable degree of heat, through which they become moist, or, in other words, are said to sweat, after which they are dried for packing.

Other species also of *Nicotiana* are said to be cultivated, especially *N. rustica* L., which yields the Turkish tobacco and is said to have been the first introduced into Europe, and is thought to have been cultivated by the aborigines of this country, as it is naturalized near the borders of some of our small Northern lakes. The *N. quadrivalvis* of Pursh affords tobacco to the Indians of the Missouri and Columbia Rivers; and *N. fruticosa*, a native of China, was probably cultivated in Asia before the discovery of this continent by Columbus. Besides these there are *N. Persica* L., cultivated in Persia, and is the source of Persian tobacco; *N. repanda* Willd., cultivated in Central and Southern North America; *N. Bigelovii* Wats., of North America. It is very doubtful, however, whether these plants furnish any large part of the commercial tobacco. Latakia tobacco seems to be the product of the *N. Tabacum*, and Senator Vidal asserts that *N. repanda* is not found in Cuba, *N. Tabacum* being the only species there cultivated. (*P. J.*, viii, 710.) Again, the Persian and Turkish tobacco sold under the name of *tumbeki*, which has been variously attributed to *N. Persica* and to *N. rustica*, is in all probability the product of *N. Tabacum*. (*Kew Bulletin*, April, 1891.)

The total annual production of tobacco throughout the world at present is estimated at 1,000,000 tons, of which Asia furnishes 350,000, America 300,000, Europe 250,000, and the rest of the world 100,000 tons. (*Zeit. für Angew. Chem.*, 1905, p. 1623.)

Tobacco, as it occurs in commerce, is of a yellowish-brown color, a strong narcotic penetrating odor which is wanting in the fresh leaves, and a bitter, nauseous, and acrid taste. These properties are imparted to water and alcohol. They are injured by long boiling, and the extract is, therefore, relatively feeble. An elaborate analysis of tobacco was made by Vauquelin, who discovered in it among other ingredients, an acrid, volatile, colorless liquid, slightly soluble in water, very soluble in alcohol, and supposed to be the active principle. It was separated by a complicated process, of which, however, the most important step was the distillation of tobacco juice with potassium hydroxide. In the results of this distillation Vauquelin recognized alkaline properties, which he ascribed to ammonia, but which were, in part at

least, dependent upon the acrid principle above mentioned. To this principle the name of *nicotine* was given; but its alkalinity was ascertained by two German chemists, Posselt and Reimann. The nicotine obtained by Vauquelin and by Posselt and Reimann was a colorless, volatile liquid, and, as subsequently ascertained by Henry and Boutron, was in fact an aqueous solution of the alkaline principle in connection with ammonia. It was reserved for these chemists to obtain nicotine in a state of purity. It exists in tobacco combined with an acid in excess, and in this state is not volatile. It is easily extracted from tobacco by means of alcohol or water as a malate, from which the alkaloid can be separated by shaking it with caustic soda solution and ether. The ether is then expelled by warming the liquid, which finally has to be mixed with slaked lime and distilled in a stream of hydrogen, when the nicotine begins to come over at about 200° C. (392° F.). The percentage of nicotine in tobacco varies considerably—from 1.62 per cent. in Havana tobacco and 2 per cent. in Maryland tobacco to 6 per cent. in Virginia tobacco and 8 per cent. in Kentucky tobacco. For a mode of estimating the proportion of nicotine in tobacco, see Harrison and Self, *P. J.*, June 1, 1912. For an analysis of the ashes of Virginia tobacco, by McD. Irby, of New Orleans, and J. A. Cabell, of Virginia, see *Chem. News* (Sept. 4, 1874, 117). For Liecke's and Schloessing's methods of estimating nicotine, see 17th edition, *U. S. D.*, p. 1346. For Kosutany's method, see *Z. An. Chem.*, 1893, 277.

Nicotine. (*Nicotina* or *Nicotia.*) β-pyridyl-α-methyl-pymolidine.—This is a colorless or nearly colorless fluid, of the sp. gr. 1.027, boiling at 247° C. (476.6° F.), and not solidifying at −10° C. (14° F.); having a faint odor when cold; of an exceedingly acrid, burning taste, even when largely diluted; entirely volatilizable, and, in the state of vapor, very irritant to the nostrils, with an odor recalling that of tobacco; inflammable; very soluble in water, alcohol, ether, the fixed oils, and oil of turpentine; strongly alkaline in its reaction, and capable of forming crystallizable salts with the acids. These salts are deliquescent, having a burning and acrid taste, and, like the salts of ammonia, lose a portion of their base by heat. While nicotine has not been prepared synthetically as yet, two isomeric bases, *isonicotine* and *nicotidine*, have been prepared. On treatment with oxidizing agents, nicotine yields *nicotinic* or *β-pyridinecarboxylic acid*, $C_5H_4N.COOH$. In its action on the animal system it is one of the most virulent poisons known. A drop of it, in the state of concentrated solution, is sufficient to destroy a dog, and small birds perish at the approach of a tube containing it. Tannin forms with it a compound of but slight solubility, and might be employed as an antidote. Nicotine exists in tobacco in small proportion; it has been found in the seeds, and, in very small proportion, in the root. There can be little doubt that tobacco owes its activity to this alkaloid, which has also been criminally employed as a poison. (*N. Y. Jour. of Med.*, N. S., ix.) Nicotine has the remarkable property of resisting decomposition amid the decaying tissues of the body, and was detected by Orfila in the bodies of animals destroyed by it two or three months after their death. Mayer concluded from his experiments that nicotine is the active principle in all parts of the plant both before and after curing. (*Proc. A. Ph. A.*, 1865.)

Although Thoms (*A. J. P.*, 1900, p. 227) was unable to detect any nicotine in tobacco smoke, there is no room for doubt that it is present in sufficient amount to be injurious. Lehmann (*P. J.*, Sept. 18, 1909) finds that about 95 per cent. of the nicotine in tobacco passes over into the smoke, and Toth (*Chem. Ztg.*, 1909, p. 866) has shown that the large proportion of nicotine exists in the smoke in uncombined state.

When distilled at a temperature above that of boiling water, tobacco affords an empyreumatic oil, which Brodie proved to be a most virulent poison. It was official in the U. S. P., 1870, under the name of *Oleum Tabaci: Oil of Tobacco.* A single drop, injected into the rectum of a cat, occasioned death in about five minutes, and double the quantity, administered in the same manner to a dog, was followed by the same result. This oil is of a dark brown color and an acrid taste, and has a very disagreeable odor exactly resembling that of tobacco pipes which have been much used. It has been stated to contain nicotine. (*Ann. Ch. Phys.*, 3e sér., ix, 465.)

It is quite certain that tobacco leaves undergo considerable chemical changes during the processes of curing and preparation for use. Thus, the characteristic odor of ordinary tobacco is entirely different from that of the fresh leaves, and must be owing to the generation of a new volatile principle. The proportion of nicotine is probably slightly diminished by the process of "curing." (See Mayer, *Proc. A. Ph. A.*, 1865.)

Medicinal Properties and Uses.—Tobacco is locally irritant. Snuffed up the nostrils, it excites violent sneezing, and a copious secretion of mucus; chewed, it irritates the mucous membrane of the mouth and increases the flow of saliva; when injected into the rectum, it sometimes operates as a cathartic; and the alkaloid nicotine injected into the cellular tissue of animals evidently produces much pain. In large doses, or in persons unaccustomed to it, tobacco produces severe nausea, sometimes vomiting, accompanied with profuse perspiration, and great muscular weakness. The alkaloid nicotine is a virulent poison. It primarily excites, and secondarily paralyzes, the ganglia upon the sympathetic nerves, stimulates the intestinal muscles, and, in sufficient quantities, has a paralytic action upon the motor nerves. As a result of its action upon the sympathetic ganglia, it causes contraction of the blood-vessels with marked increase in the blood pressure, followed, after large doses, with vascular dilatation and fall of pressure. The pulse rate is at first decreased, later becomes rapid. There is primary increase in the secretion of the salivary and probably of the other glands, followed, after large doses, by paralysis of secretions.

The use of tobacco was adopted by the Spaniards from the American Indians. In the year 1560 it was introduced into France by the ambassador of that country at the court of Lisbon, whose name—Nicot—has been perpetuated in the generic title of the plant. Sir Walter Raleigh is said to have introduced the practice of smoking into England. In the various modes of smoking, chewing, and snuffing, the drug is now largely consumed in every country on the globe. It must have properties peculiarly adapted to the propensities of our nature to have thus surmounted the first repugnance to its odor and taste and to have become the passion of so many millions. Whether or not nicotine plays any part in the pleasurable effects of tobacco is, despite considerable research and discussion, unsettled, but it is generally agreed that the evil

effects of excessive indulgence are due to this alkaloid. The most important disturbances produced are in the digestive and circulatory organs. As a result of the disturbed innervation of the heart, palpitation and cardiac irregularities are common, and the vascular contraction is generally regarded as one of the causes of arterial degenerations.

Formerly much used as a relaxant, tobacco has been superseded by safer and more efficacious remedies, so that it is at present never employed in medicine, except occasionally in *chronic asthma.* It should always be borne in mind that its active principle is absorbed readily by the skin, and that serious or even fatal poisoning may result from its too free application to the surface of the body. A case of death is on record, occurring in a child eight years old, in consequence of the application of the expressed juice of the leaves to the head, for the cure of *tinea capitis.* Death has also been produced by the inhalation of the smoke.

From five to six grains (0.32–0.4 Gm.) of powdered tobacco will generally act as an emetic; but should never be used for this purpose.

Toddalia. *Br. Add.* 1900.—"The dried root-bark of *Toddalia aculeata* Lam." (Fam. *Rutaceæ.*) This climbing shrub, known also as *Lopez root,* growing in East Africa, Madagascar, the subtropical Himalayas, Ceylon, and the Philippines, is a tonic stomachic, containing a resin and a volatile oil, which may be readily obtained from the leaves by distillation. This oil has the odor of citron peel, and a bitter, aromatic taste. See also *Schim. Rep.,* 1906, 82, and 1912, 121. The British Addendum recognized an *infusion* (*Infusum Toddaliæ,* two ounces to a pint), *dose,* one to two fluidounces (30–60 mils); also a *concentrated solution* (*Liquor Toddaliæ Concentratus,* Br. Add., 1900), *dose,* from one-half to one fluidrachm (1.8–3.75 mils).

Tolypyrine. *Tolyantipyrine. Paratolyl-dimethyl-pyrazole.* $C_{12}H_{14}ON_2$.—This compound occurs in colorless crystals soluble in water and alcohol, insoluble in ether, and is used like antipyrine as an antipyretic in *doses* of from eight to thirty grains (0.5–2.0 Gm.).

Tolysal. *Tolypyrine Salicylate.* ($C_{12}H_{14}N_2O$ $C_7H_6O_3$.)—This has been used in *rheumatism. Dose,* ten to fifteen grains (0.6–1 Gm.).

Tonga.—*Tonga Bark* is a composition of unknown barks compounded by the natives of the Feejee Islands for medicinal purposes. The plants from which this remedy is derived are believed to be *Premna taitensis* Schan. (Fam. *Verbenaceæ*), and *Epipremnum mirabile* Schott. (Fam. *Araceæ.*) According to Moeller (*Ph. Centrh.*), the latter is not a source of tonga. (*A. J. P.,* 1881, 439.) It was introduced to the notice of the medical profession by Sydney Ringer and Wm. Murrell, of London, as a remedy for *neuralgia.* (*L. L.,* ii, 1880.) Merck reports the presence of *tongine* and a volatile oil in tonga. (*Merck's Index,* 1907.) The natives are said to steep the bundle as prepared by them for twenty minutes in half a tumberful of cold water, and then, squeezing it dry, drink the infusion, preserving the bundle in a dry place for further use. A fluidextract has been put upon the market, and evidence of its value brought forward, but we have known a fluidrachm of this extract to be given every two hours for two days without obvious effect; the *dose* usually recommended is half a fluidrachm (1.8 mils).

Tonka Bean. *Fève Tonka,* Fr. *Tonka-bohnen,* G.—The seeds of *Coumarouna odorata* of Aublet, a large tree growing in Guiana and Northern Brazil which yields the Dutch Tonka Bean; and of *C. appositifolia* (Aubl.) Tanb, which is the source of the English tonka bean. The fruit is an oblong-ovate pod, enclosing a single seed, from 3 to 4 cm. long and about 1 cm. wide, usually somewhat compressed, with a dark brown, wrinkled, shining, thin, and brittle skin, and a light brown, oily kernel. The seed has a strong, agreeable, aromatic odor, and a bitterish, aromatic taste. Its active constituent is a crystallizable, odorous substance, called *coumarin* or *cumarin,* $C_9H_6O_2$ (see page 1345). It is the anhydride of *coumaric acid,* $C_9H_8O_3$. It is capable of sublimation; but, to obtain it in crystals in this way, a low temperature is necessary. (Waddington, *P. J.,* 1868, 410.) This substance is sometimes found in a crystalline state, between the two lobes of the kernel. Coumarin appears to be a widely spread substance which has been found in many species of plants, notably in species of *Melilotus* (fam. *Leguminosæ*), sweet vernal grass (*Anthoxanthum odoratum* L.), and related grasses, and *Trilisa odoratissima* (Walt.), Cass. (*Liatris odoratissima* Willd.) (fam. *Compositæ*), a plant sometimes used to protect woollens from moths. (*A. J. P.,* 1859, 556; also 1899, 133; see also *Chem. Gaz.,* 1852; *D. C.,* Nov., 1887.) Gössmann obtains coumarin in the following manner. The beans, cut finely, are heated for a long time with an equal bulk of alcohol of specific gravity 0.863, nearly to boiling, and, the tincture being decanted, the residue is treated in the same manner. The tinctures are mixed, the alcohol distilled off until turbidness appears, when four times the bulk of water is added, which precipitates coumarin and fatty matter. The precipitate is then heated to boiling, and the liquid passed through a moistened filter. The fatty matter remains on the filter, and the hot solution which passes deposits the coumarin on cooling. More may be obtained by concentrating the liquid, and may be purified by animal charcoal. One pound of the beans yielded 108 grains of coumarin. Coumarin has been prepared synthetically by heating salicylic aldehyde with sodium acetate and acetic anhydride, whereby *acetocoumaric acid* is formed, which decomposes further into acetic acid and coumarin. It has also been obtained by the action of phenol upon the malic acid. Tonka bean is used to adulterate tincture and extract of vanilla and to flavor snuff, being either mixed with it in the state of powder or put entire into the snuff box. Coumarin adulterated with acetanilid has been found in the market. (*Schim. Rep.,* 1893, 67.) *Tonquin butter* is an article of commerce in Holland. It is the fatty substance of tonka beans; it was analyzed by M. Duyk, it has the sp. gr. of 0.888, melting point is 28° C. (82.4° F.), saponification number 25.7. (*Rep. de Pharm.,* 1908.)

Ellinger (*A. E. P. P.,* 1908, Suppl.) found the fatal dose of coumarin for the rabbit to be 0.3 Gm. per kilo. He confirmed the statement of Köhler (*Cb. M. W.,* 1875) that it acted as a narcotic, but could not find evidence of cardiac depression. The fluidextract of the bean has been used with asserted advantage in *whooping cough* in *doses* equivalent to from five to eight grains (0.32–0.5 Gm.) for children five years old. (*A. J. P.,* 1869, 27.)

Tormentil. *Rhizoma Tormentillæ,* P. G. *Tormentille,* Fr. *Tormentillwurzel,* G. *Tormentilla,* It. *Tormentila,* Sp.—Various species of the rosaceous genus *Potentilla* have been employed in medicine. (See *A. J. P.,* 1875, 109.) It is asserted

that our common *P. canadensis* L. is a valuable sudorific and diuretic.

Potentilla Tormentilla Neck. (*Tormentilla erecta* L., *T. officinalis* Curt.)—The tormentil, or *septfoil*, which was formerly in the Secondary List of the U. S. Pharmacopœia, is a small perennial plant of Europe and Asia. All parts of the plant are astringent, especially the rhizome, which is the part employed. The rhizome of *tormentil* is cylindrical, somewhat fusiform, branching and more or less curved, from 2.5 to 8 cm. long, and from 0.5 to 1.5 cm. thick, brown or blackish externally, and reddish within. It has a slight aromatic odor and a very astringent taste. It contains a red coloring principle, soluble in alcohol, but insoluble in water, and considerable quantities of a peculiar tannin (*tormentil-tannic acid*, $C_{26}H_{22}O_{11}$). Rembold found that tormentilla red has the same composition as rhatany red, and yields the same products of decomposition when fused with potassium hydroxide. He also obtained *kinovic acid*, $C_{24}H_{38}O_4$, and small quantities of *ellagic acid*, $C_{14}H_6O_8$. (*A. J. P.*, 1868, 311; from *Ann. Chem.*, cxliv, 5.) The root is said to be used for tanning leather in the Orkneys and Western Islands of Scotland, and for staining leather red by the Laplanders. Tormentil is a simple and powerful astringent, applicable to all cases of disease in which this class of medicines is indicated. It may be given in substance, decoction, or extract. The *dose* of the powder is from thirty grains to a drachm (2.0–3.9 Gm.).

Toxicodendron Capense Thunb. (Fam. *Euphorbiaceæ.*)—The fruits of this South African species are said to be used for the poisoning of hyenas. They have been investigated by von Engelhardt (*Kobert's Arbeiten*, 1892), who finds in them a neutral, bitter principle, *hyananchin*, which is a powerful poison, resembling strychnine in its physiological action, from which, however, it differs in that it powerfully affects the cerebrum. The convulsions which it produces are of central origin, the poison having no action upon the nerve trunks or the muscles.

Toxylon. *Maclura pomifera* (Raf.) Schneider. (*Maclura aurantiaca* Nutt.) (Fam. *Moraceæ.*) *Osage Orange.*—The bark of the root of this tree, which is indigenous in the Southern United States, is said to be considerably used in making a yellow dye. Alex. King has found in it *moric* and *moritannic acids*. (*A. J. P.*, xlvi, 257.)

Toxynon. *Sodium-acet-amino-mercury benzoate.*—This mercurial preparation, according to Gutmann (*B. K. W.*, 1913), contains 48 per cent. of mercury. He recommends it for intravenous injection in the treatment of *syphilis*. The *dose* is one and one-half to three grains (0.096–0.2 Gm.) every alternate day.

Tradescantia Erecta Jacq. (Now *Tinantia fugax* Scheidw.) (Fam. *Commelinaceæ.*)—The natives of South America used an extract of this plant as a hæmostatic in cock-fights and it has lately been introduced into medicine, being especially recommended in *hemorrhages of the ear and the upper air passages*. Nothing definite is known of its actual composition and its styptic virtue has been ascribed, by some, to its tannin content. For description of *Commelina communis*, a perennial herb of the United States, see Preston, *A. J. P.*, 1898, p. 321.

Tragoponic Acid.—This was found by Rademaker and Fisher in the seeds of *Tragopogon porrifolius* L. (Fam. *Compositæ.*) *Salsify*, more commonly known as *oyster plant*, is the plant which furnishes the edible root. (See *Nat. Drug.*, July 23, 1886, 47.)

Traumatol. *Iodocresine. Iodocresol.* $C_6H_3I.(CH_3)OH$.—This occurs as a purplish-red or yellow powder; it is obtained by acting on cresol with iodine, and is used as a substitute for iodoform.

Tribrom Beta-naphthol. $C_{10}H_4Br_3OH$.—This occurs as a greyish crystalline powder, readily soluble in alcohol, ether and the alkalies. Lehmann (*Beitr. Klin. Chir.*, 1911, xlvii) has used it for the purpose of disinfecting the hands of the surgeon. He uses an alcoholic solution containing 0.5 per cent.

Tribromhydrin. (*Tribromhydrinum. Allyl Tribromide, Tribromaliyl, Tribrompropane, Propargyl Tribromide.* $CH_2Br.CHBr.CH_2Br$.—This substance is a colorless or faintly yellowish liquid at the ordinary temperature, but solidifying when cooled below 10° C. (50° F.) to a mass having a specific gravity of 2.430 at 15° C. (59° F.). Its boiling point is about 220° C. (428° F.) and is soluble in alcohol or ether. It has been recommended by De Fleury as a nerve sedative in *hysteria, asthma, whooping cough*, and other nervous disorders. It may be administered by mouth in capsules containing each five drops (0.25 mil), of which one or two may be given several times a day. It has also been employed subcutaneously in two to three minim (0.12–0.2 mil) doses in 20 minims of ether. (*Ph. Post*, Dec., 1888.)

Tribromphenol. $C_6H_2Br_3.OH$.—*Tribromphenol* is prepared by shaking a solution of phenol with bromine water. It occurs in the form of soft, white, colorless needles, melting at 95° C. (203° F.), and subliming undecomposed at a higher temperature. It is soluble in alcohol, ether and chloroform, and soluble with difficulty in glycerin, liquefied phenol, water and weak alcohol. In caustic alkaline solutions it is readily soluble, and from them it is separated unaltered by acids.

As pointed out on page 0000, the introduction of a halogen into its molecule increases the antibacterial properties of phenol. Bechold and Ehrlich (*Cb. C.*, 1906, xlvii) have found that tribromphenol will inhibit the growth of bacteria when present in 1 part in 10,000. Grimm, who recommends tribromphenol as a surgical antiseptic, states that a half per cent. solution will kill the bacteria of putrefaction in an hour.

Tribromphenol-bismuth. *Xeroform.* $Bi_2O_3(C_6H_2Br_3OH)$.—This is a yellowish-green, insoluble, almost odorless and tasteless powder, which, according to its manufacture, is a chemical combination of equal amounts of bismuth and tribromphenol, containing about 50 per cent. of bismuth oxide.

Xeroform has been widely used as a substitute for iodoform in various surgical procedures. The advantages claimed for it are that it is not only practically odorless, it is also non-toxic, and that it exercises a more powerful antiseptic effect. It appears also to possess to a considerable degree the analgesic action, as well as the desiccating and antiseptic effect of iodoform on *wounds*. It has also been employed as a substitute for the salts of bismuth in the treatment of *enteritis, gastric ulcer* and similar conditions. For the latter purpose it is administered in *doses* of from 8 to 15 grains (0.5–1.0 Gm.).

Tribromphenol Bromide. $C_6H_2Br_3OBr$.—E. W. Lewis finds that the melting point usually attributed to this substance 47.8° C. (118° F.), is much too low, and tnat it may be raised to

148° to 149° F. (64.4°–65° C.) by recrystallizing the compound from ethyl acetate; moreover, while, as usually stated, the substance of low melting point gives off bromine on heating at about 125° F. (51.7° C.), the purified material begins to lose bromine before melting at about 145° F. (62.8° C.). *Tribromphenol bromide* is made by adding 2 to 4 Gm. of phenol dissolved in water to bromine water containing 19 Gm. of bromine. After each addition of phenol the bottle is vigorously shaken, and when all of the phenol is added the mixture is set aside in a dark place for three days; the precipitate is then collected, drained on a porous earthenware tile and dried over sulphuric acid; the precipitate is then dissolved in warm ethyl acetate and the solution on cooling deposits the crystals. The crystals of tribromphenol bromide belong to the orthorhombic system. It forms citron-yellow scales which are insoluble in water, ether, cold alcohol and alkalies. On boiling with alcohol it is decomposed and tribromphenol results.

Triferrin, *N. N. R.* 1917, or *paranucleinate of iron*, contains about 22 per cent. of iron as well as 2.5 per cent. of organically combined phosphorus and is prepared from casein of cow's milk by digestion and precipitation by means of ferric salts. *Triferrin* is freely and completely soluble in a weak solution of sodium hydroxide, but it is insoluble in diluted hydrochloric acid having the acid strength of normal gastric juice. *Dose*, five grains (0.32 Gm.).

Trifolium. *N. F. IV. Red Clover Blossoms.*—"The dried inflorescence of *Trifolium pratense* Linné (Fam. *Leguminosæ*)." *N. F.* It is described in the N. F. as "Heads are ovoid with rounded summit, mostly from 12 to 25 mm. in length and breadth, shriveled, purplish and more or less brown from drying, consisting of many small papillonaceous flowers, crowded together and clothed at the base with broad, pointed, ciliate stipules of a pale green color with darker veins and which may or may not be accompanied by diminutive trifoliate leaves. The individual flowers are from 12 to 15 mm. in length, longer than the four nearly equal teeth and shorter than the narrower fifth tooth, calyx-teet subulate, tapering; petals united into a tube below, the standard longer than the wings, but when recurved appearing shorter; stamens diadelphous (nine and one); style slender. The odor is faintly aromatic and somewhat tea-like, the taste being sweetish, then slightly bitter. Trifolium yields not more than 10 per cent. of ash."

Red clover blossoms were introduced into the N. F. IV and are used to make the fluidextract (see Part III). For the results of a research of the constituents of *T. pratense* by Power and Solvay, see *C. D.*, 1910, 273. Clover has, by the superstitious, been supposed to possess alterative properties. It also enters into the composition of some antiasthmatic cigarettes. There is, however, no sufficient reason to suspect it of any medicinal virtue.

Trigemin. *Dimethyl-amido-antipyrin-butyl-chloral hydrate.* $C_{17}H_{24}N_3O_3Cl_3$.—A product of the action of butyl chloral hydrate on pyramidon, forming long white needles, fusing at 85° C. (185° F.) and possessing a delicate aromatic odor and a mild taste. It has been used as an analgesic in all those forms of pain for which the coal-tar derivatives are valuable. It is incompatible with spirit of nitrous ether, acacia and most of the chemicals that are so with antipyrin. The *dose* is from three to fifteen grains (0.2–1.0 Gm.).

Trigonella. *Greek Hay Seed. T. Fœnum-græcum* L. *Fenugreek. Semen Fœnugræci*, P. G. *Bockshornsamen*, G.—A European annual leguminous plant cultivated in Southern Europe, Northern Africa and India for its seeds. These are oblong-cylindrical, somewhat compressed, obliquely truncated at each extremity, 3 to 5 mm. in length, brownish yellow externally, internally yellow and marked with an oblique furrow running half their length. They have a strong peculiar odor resembling that of elm bark, and an oily, bitterish, farinaceous taste, and contain fixed and volatile oils, mucilage, bitter extractive and a yellow coloring substance. E. Jahns (*Ber. d. Chem. Ges.*, xviii, 2518–2523) has obtained *choline*, $C_5H_{15}NO_2$, and *trigonelline*, $C_7H_7NO_2$. The yield of the former was 0.05 per cent., and of the latter 0.13 per cent. Trigonelline is isomeric and probably identical with pyridine-betaine. By heating trigonelline with concentrated solution of potassium hydroxide, a distillate is obtained which appears to contain pyridine. An ounce of the seeds, boiled in a pint of water, renders it thick and slimy. They yield the whole of their odor and taste to alcohol. On the continent of Europe they are employed in the preparation of emollient cataplasms, enemata, ointments and plasters. They are never used internally for human beings, but the ground seeds are used to an enormous extent in the manufacture of cattle powders or condition powders and to give a maple flavor to confectionery.

Tri-iodophenol Bismuth.—Because of the success of tribromphenol-bismuth the homologous iodine compound has been introduced under the name of *neoform*. It is a yellow powder insoluble in all the ordinary solvents and is used as a surgical dusting powder.

Trillium. *N. F. IV. Beth Root. Birth Root. Wake Robin. Trillium*, Fr., G.—"The dried rhizomes of *Trillium erectum* Linné and closely allied species of *Trillium* (Fam. *Liliaceæ*)." *N. F.*

It is described in the N. F. as follows: "Rhizome oblique, globular, oblong or obconical, truncate, below, terminated by a small bud surrounded by a sheath of scarious leaf bases, annulated by leaf scars and fissured by stem scars. It is from 0.6 to 5 cm. in length and from 0.6 to 2.5 cm. in width, more or less compressed laterally, rootlet scars in several concentric rows on the under side in the upper portions. Externally yellowish to reddish-brown; internally of a pale yellow; fracture somewhat uneven with a more or less spongy appearance. Odor distinct; taste bitter and acrid with a sensation of warmth in the throat and when chewed causing an increased flow of saliva. Trillium yields not more than 5 per cent. of ash."

The indigenous species, *T. erectum* L. is said to have been employed by the aborigines, and also used by the early settlers; it still has some vogue under the name of *beth root* as an astringent and tonic expectorant; also in *hemorrhages* and to hasten *parturition* and as a local irritant in *skin diseases*. *Dose*, of powdered root, a drachm (3.9 Gm.) three times a day. E. S. Wayne found in it a substance supposed to be saponin. It is said also to contain volatile oil and tannic acid. D. J. Prendergast believes that the *Trillium erectum* contains a glucoside similar to convallamarin. (*Am. Drug.*, Nov., 1887.) For details, see 16th edition, *U. S. D.* Vivian I. Reid (*A. J. P.*, 1892, 67) found a small quantity of fixed oil, saponin to the extent of 4.86 per cent. and an acid crystalline principle which is colored purplish-brown by sulphuric acid and light green with sulphuric acid and potassium dichromate.

This rhizome was introduced into the N. F. IV to use in the preparation of the *fluidextract of trillium* with three volumes of alcohol and one volume of water. The fluidextract is an ingredient in *compound elixir of viburnum opulus.*

Trimethylamine. *Secaline.* $CH_3CH_3CH_3N$.—This substance which has been so often confused with propylamine (see p. 1563) is a colorless liquefiable gas of a fishy ammoniacal odor, soluble in water and alcohol and having at 0° C. (32° F.) specific gravity of 0.673, boiling at 9° to 10° C. (48.2–50° F.) and possessing extremely toxic properties. It was first prepared by Wertheim in 1850 from narcotine and was given the name *metacetamine.* The common method of preparing this substance of the present time is by the action of ammonia gas on methyl iodide. The aqueous solution of *trimethylamine* is often miscalled "propylamine," which is a primary compound of ammonia [monamine (which see)], whereas the trimethylamine is a tertiary compound ammonia (triamine). It is not used medicinally.

The hydrochloride, $(CH_3)_3NHCl$, is used as an odorous addition to bait, to lure fish.

Triosteum. *T. perfoliatum* L. *Horse Gentian. Bastard Ipecac. Tinker's Weed. Wild Coffee. Fever Root. Feverwort. Wild Ipecac. Racine de Trioste,* Fr. *Dreisteinwurzel,* G. (Fam. *Caprifoliaceæ.*)—This plant is found in rich woods from Massachusetts to Alabama and westward to Nebraska, preferring a limestone soil and shady situations. The rhizome or root, the part used, is horizontal, long, about 15 mm. in diameter, thicker and tuberculated near the origin of the stem, of a yellowish or brownish color externally, whitish within, and furnished with fibers which may be considered as branches of the main root. When dry it is brittle and easily pulverized. On microscopic examination, numerous crystals of calcium oxalate are to be seen. It has a sickening odor, and a bitter, nauseous taste. It is said to contain an alkaloid which Andree believed to be identical with emetine, but which Hartwich has shown to be different. It yields its active properties to both water and alcohol. Triosteum is cathartic, and in large doses emetic and perhaps diuretic. The bark of the root may be given in *doses* of twenty to thirty grains (1.3–2.0 Gm.), or the extract in half the quantity. For uses, see *A. J. P.,* 1891, 326.

Triphenin. *Propionyl-phenetidin.* $C_6H_4.C_2H_5O.NH.(CH_3.CH_2.CO)$.—A homologue of phenacetin made by boiling a mixture of paraphenetidin with propionic acid; it forms colorless, odorless crystals, using at 120° C. (268° F.), of feebly bitter taste, soluble in 2000 parts of water and its incompatibles are the same as those of phenacetin.

Triphenin has been used to a limited extent as an antipyretic in *typhoid fever, pneumonia,* and other acute affections, and also as an analgesic for nervous pains. Its range of action is precisely that of phenacetin. *Dose,* eight to fifteen grains (0.5–1.0 Gm.).

Tripoli. *Terra Tripolitana.*—An earthy mineral, of a whitish, yellowish, or pale straw color, sometimes inclining to red or brown, usually friable, often adhesive to the tongue, and presenting the aspect of argillaceous earth, though differing from clay by the roughness and hardness of its particles, and by not forming a paste with water. The *Venice tripoli* is said to come from Corfu. Tripoli is sometimes artificially prepared by calcining certain argillites. It is used for cleaning and polishing metals.

Trompatila.—This is the stem and branches of *Bouvardia triphylla* Salisb. (fam. *Rubiaceæ*), a Mexican plant used by the natives for *hydrophobia.* (*A. J. P.,* 1874, 51.)

Tropacocaine. *N. N. R.* 1917. *Benzoyl-pseudotropeine.* $C_8H_{14}NO.C_7H_5O$.—This compound, belonging chemically to the class of *Tropeines* (see *Atropine*), was isolated by Geisel from a narrow-leaved coca plant from Java. (*Ber. d. Chem. Ges.,* xxiv, p. 2336.) It is obtained as an oil, which when quite dry solidifies in radiating crystals, melting at 49° C. (120.2° F.). It has a strong alkaline reaction, and is easily soluble in alcohol, ether, chloroform, benzene, and petroleum benzin. The *hydrochloride,* being freely soluble in water, is usually preferred to the base. It is decomposed by heating with hydrochloric acid into benzoic acid and pseudotropine, $C_8H_{15}NO$.

Tropacocaine resembles cocaine in its stimulant action upon the nerve centers, and also in its local anesthetic action. It differs from cocaine, however, in that it does not cause local constriction of the blood vessels, and that it has very little influence upon the pupil. It is also decidedly less toxic than cocaine. It has been used chiefly in the so-called spinal anesthesia and a large number of surgeons have reported favorably upon it. A *dose* of one grain (0.06 Gm.) is ordinarily recommended, although a number of authors have used larger quantities without evil effects. Tropococaine has been used also as a local anesthetic in ophthalmic and pharyngological practice. It possesses an advantage over cocaine in being more stable in solution and easily sterilizable.

Trypan Blue. *Diamine blue. Congo blue. Azidin blue. Niagara blue. Sodium salt of tolidin-disazo-bi-l-amido-8-naphthol-3, 6-disulphonic acid.*—It has been used as a dyestuff. Recently a purified form of this dye has been brought forward as a therapeutic remedy in various protozoan infections. It occurs as a bluish-gray powder which forms in water a deep violet-blue solution. It is almost insoluble in alcohol and quite so in ether. We do not know of any reports of its use in human beings, but Evers, Zengel (*B. Thier W.,* 1913) and others have reported rapid cures of both *malaria* and *trypanosomiasis* in the lower animals.

Trypan Red. *Sodium salt of ortho-benzidine-mono-sulpho-acid-disazo-bi-2-naphthylamine-3.6-sulpho-acid.* $C_{10}H_4(NaSO_3)_2NH_2N.N(C_6H_4)(C_6H_3)NaSO_3N.NC_{10}H_4(NaSO_3)_2NH_2$.—By *trypan red* is meant a coloring matter allied to *benzo-purpurin B,* or to *Brilliant Congo R.* It is a reddish-brown powder, soluble in water. The aqueous solution is not altered by the addition of acetic acid, but on the addition of a sufficient quantity of hydrochloric acid, the free sulpho-acid is eliminated in blue flakes.

This was brought forward by Ehrlich and Shiga (*B. K. W.,* 1904) as a useful remedy in experimental, and a hopeful remedy in human *trypanosomiasis.* Jaboulay and one or two other French writers (*Lyons Medicale,* 1905) have used it hypodermically in the treatment of *cancers* with asserted extraordinary benefit, but the remedy has failed to come into general use. Eight grains (0.5 Gm.) of the remedy may be injected hypodermically, dissolved in 40 mils of physiological salt solution, at intervals of from two to ten days.

Tulipine.—An alkaloid extracted from the garden tulip, *Tulipa* and of which there are a number

of classes depending upon the order of their flowering. It is said to be a cardiac poison, with remarkable sialagogue properties. (*Nouv. Rem.*, 1886.) Under the name of *chielin* there has been put upon the market a brownish thick extract-like substance of an agreeable odor, easily soluble in water, said to be derived from the bulb of the tulip and to be non-poisonous. It has been highly recommended by H. Heyman as a soothing application in various forms of inflammatory skin diseases. (*D. M. W.*, August, 1902.)

Tumenol.— *N. N. R.* 1917. A dark brown or brownish-black liquid, of a syrupy consistence, which is made from bituminous shale oils. These are agitated with sodium hydroxide solution to remove phenols and then with sulphuric acid to remove pyridine and other bases. The oil is then treated with fuming sulphuric acid. The dark syrupy liquid which separates is washed with water and dissolved in sodium hydroxide. From this solution ether extracts *tumenol oil.* Hydrochloric acid, on the other hand, if added to the sodium hydroxide solution, throws down *tumenol-sulphonic acid.* A mixture of these two substances constitutes *tumenol venale*, a soft, resinous, odorless mass. A. Neisser (*D. M. W.*, 1891) highly commends tumenol as a local application in *eczema* and as having extraordinary powers over the itching of *prurigo, parasitic dermatitis* and other *skin affections.* He uses a lotion made with equal parts of ether, rectified spirit and water or glycerin and 10 per cent. of tumenol.

Turicin.—A compound of tannin (21 per cent.) with glutenin, which forms a fine inodorous, tasteless, flesh-colored powder, insoluble in water and dilute acids. Weak alkalies impart to a solution of *turicin* a rose-red color and the stronger alkalies a blood-red color. It is employed as an intestinal astringent in five to fifteen grain *doses.* It is incompatible with iron and alkalies, acacia and arsenic solutions.

Tussol. *Antipyrine Mandelate* (*Phenyl-glycolate*). $C_{11}H_{12}N_2O.C_6H_5CH(OH)COOH$.—It forms a white powder, fusing at 52° to 53° C. (125.6°–127.4° F.), is soluble in water and incompatible with most of the substances that are incompatible with antipyrine. It is recommended in the treatment of *whooping cough* in the following *doses:* for children under one year, from three-fourths to one and a half grains (0.048–0.096 Gm.); from two to four years, four to six grains (0.26–0.4 Gm.).

Tutty. *Tutia. Impure Oxide of Zinc.*—This oxide is formed during the smelting of lead ores containing zinc. It is deposited in the chimneys of the furnaces, in the form of incrustations, moderately hard and heavy, and studded over with small protuberances of a brownish color on the outside and yellowish within. As it occurs in commerce, the pieces occasionally present a bluish cast, from the presence of small particles of metallic zinc. Sometimes a spurious substance is sold for *tutty*, consisting of a mixture of blue clay and copper filings, made into a paste with water and dried on an iron rod. It is distinguished from the genuine tutty by its diffusing in water and exhaling an earthy odor, and by its greater friability. Tutty is used solely as an external desiccant. To fit it for medicinal use it must be reduced to fine powder, which is dusted over the affected part, or applied in the form of an ointment.

Tylophora Leaves. *Tylophoræ Folia. Br. Add.* (Fam. *Asclepiadaceæ.*)—The dried leaves of *Tylophora asthmatica* (L.) Wight and Arnott, are used in certain parts of India as a poison for vermin, and have been used with fatal results as a poison. *Tylophora asthmatica*, which grows in Bengal, Burmah and Ceylon, has been known in Indian medicine since 1780, and has been largely used in both the civil and the military medical service of Madras. It is officially described as "petiolate, entire, from two to five inches (five to twelve and a half centimeters) long and from three-quarters of an inch to two and one-half inches (eighteen to sixty-five millimeters) broad, lanceolate-ovate or ovate or subrotund in outline, somewhat cordate at the base, abruptly acuminated; rather leathery in texture, glabrous on the upper surface, and finely downy on the lower; of a brownish-green color, which is paler on the lower surface. Odor slightly aromatic; almost devoid of taste." *Br. Add.*

David Hooper has separated from this drug an alkaloid, *tylophorine*, soluble in ether and alcohol, but scarcely so in water; forming crystalline salts, and striking with nitric acid a purplish-red color, with Fröhde's reagents a deep sap-green, and with potassium dichromate and sulphuric acid a dirty violet. Tylophora resembles in its activity ipecac, and is used as a substitute for that drug in *bronchitis* and in *dysentery.* In *doses* of from twenty to thirty grains (1.3–2.0 Gm.) it is used as an emetic. The expectorant *dose* is from one-half to two grains (0.032–0.13 Gm.).

Tyramine. *N. N. R.* 1917.—One of the active bases which was found in ergot by Barger and Dale was *para-hydroxy-phenyl-ethylamine*, which had previously been found by Barber and Walpole as one of the decomposition products in putrid meat infusion. This base is now prepared synthetically, and marketed under the trade-name of "*tyramine.*" In a general way the physiological action of tyramine is similar to that of epinephrine, but it is very much less powerful, and produces practically no effect when applied locally to the mucous membranes. It is recommended only as an internal remedy, as a circulatory stimulant in *shock* and *collapse* and as a uterine stimulant. There is not sufficient clinical evidence to justify a conclusion as to its practical usefulness. The *dose* is from one-third to one grain (0.02 to 0.065 Gm.).

Ulex. *Ulex europœus* L. (Fam. *Leguminosæ*), is the common *furze, gorse,* or *whin* so conspicuous in the waste places and by the roadsides of Great Britain, from its spiny branches and bright yellow flowers situated on the spines, either solitary or in pairs. The young tops are fed to cattle and horses, but the food value has been questioned. The leaf buds have been used as a substitute for tea and the flowers yield a beautiful yellow dye. In the seeds of this plant, A. W. Gerrard has found an alkaloid, *ulexine.* In 1890 Kobert (*D. M. W.*, 1890), as the result of an elaborate physiological study, came to the conclusion that ulexine and cytisine are identical. The suggestion has given rise to a considerable chemico-physiological discussion, a brief abstract of which may be found in *P. J.*, Feb., 1891. Kobert found indications of a second alkaloid in ulex. Partheil (*A. Pharm.*, 1892, 448; 1894, 486) and Plugge (*A. Pharm.*, 1894, 444) are in accord as to the identity of ulexine and cytisine. Ulexine has been used in cardiac *dropsy. Dose*, from one-fifteenth to one-twentieth of a grain (0.004–0.003 Gm.).

Ulmaren is the name given by Bourcet to a

mixture of the salicylic acid esters of the higher aliphatic alcohols. It has been stated to contain 75 per cent. of salicylic acid. *Ulmaren* is described as a heavy, pale yellowish-red, refractive, neutral, or weakly acid liquid, of pleasant, faint odor recalling salol, and burning taste. Its sp. gr. at 15° C. (59° F.) is 1.06; and its boiling point lies between 237° C. and 242° C. (458.6°–467.6° F.). It crystallizes from an equal volume of petroleum benzin, and is almost insoluble in water, but is soluble in alcohol, ether and chloroform. Animal experimentation (*Th. M.*, 1903, xvii) showed that in moderate doses it is well taken, but if given in large doses by the mouth causes in the dog vomiting and purging, and in the rabbit a dose of 0.07 Gm. per kilogramme intraperitoneally injected, caused death from asphyxia. It is recommended to be used as an external application in *rheumatic* and *neuralgic* diseases, as well as in *gout*, either to be painted on the part and covered with waxed paper or used in the form of an ointment made up with lanolin, in which case it should be present in the proportion of 30 per cent. After epidermatic application the salicylic acid reaction may be demonstrated in the urine in three hours and lasts for three days. It is affirmed to have marked analgesic, antipyretic and antirheumatic powers. (*B. G. T.*, June, 1903.) *Dose*, fifteen to forty-five grains (1–3 Gm.); externally thirty to sixty grains (2–3.9 Gm.).

Ultramarine. *Outremer*, Fr. *Ultramarin*, G.—This fine blue pigment was formerly obtained from *lapis lazuli*, or *lazulite*, a mineral of Siberia. It is now prepared artificially on a very large scale. In preparing it, a mixture of soft clay with sodium sulphate, charcoal, caustic soda and sulphur is heated in crucibles. In this way a colorless compound is first produced, termed white ultramarine. This, however, soon becomes of a green color. The green ultramarine thus obtained, which is also used as a color, is then mixed with sulphur and heated. The sulphur takes fire and is allowed to burn in the air, when the product becomes of a fine blue color. (*Roscoe and Schlorlemmer*, vol. ii, 459.) It is thought to be a compound of aluminum and sodium silicates with sodium polysulphide, although the sulphur present is retained in two conditions, part being deposited when ultramarine is treated with acids and part escaping as hydrogen sulphide.

Umbellularia. *Umbellularia californica* (Arn.) Nutt. *California Laurel. California Sassafras. Spice Tree.* (Fam. *Lauraceæ*).—The leaves of this California tree are employed in *neuralgic headaches*, and in *intestinal colic* and *atonic diarrhea;* also externally as a mild counter-irritant. Stillman and O'Neill (*N. R.*, 1883) obtained from the seeds a new acid, *umbellulic acid*. The leaves are said also to contain about 4 per cent. of a volatile oil, having a specific gravity of 0.936, a warm camphoraceous taste, and a strong pungent odor. Burse has separated from the oil by fractional distillation *umbillol*, an oil having the formula $C_9H_{12}O$, which dissolves in concentrated sulphuric acid with red color, and is narcotic. (*Ap. Ztg.*, xi.) According to Schimmel & Co. (*Schim. Rep.*, April, 1897), it also contained *cineol*, $C_{10}H_{18}O$. It is probable that the volatile oil is a strong local anesthetic, as it has been found to act rapidly when brought in contact with exposed pulp or sensitive dentine. The fluidextract has been used in *doses* of from ten to thirty minims (0.6–1.8 mils).

Umber. *Terra Umbra.*—A mineral of a fine compact texture, light, dry to the touch, shining when rubbed by the nail, and of a fine pale brown color, which changes to a peculiar beautiful deep brown by heat. According to Klaproth, it contains 13 parts of silica, 5 of alumina, 48 of ferric oxide, 20 of manganese, and 14 of water in 100. *Burnt umber*, as well as the mineral in its unaltered state, is used in painting. The umber of commerce is said to be brought chiefly from the island of Cyprus.

Uranium.—U = 238.5. The salts of the metal uranium are violent poisons, producing not only severe *gastro-enteritis* and *nephritis*, but alst acting specifically on the hemoglobin of the blood, affecting its oxygenating powers. (See *P. J.*, Sept., 1890; Oct. 30, 1897.) They have been carefully investigated by Jacob Woroschilsky (*Arbeiten d. Pharm. Inst.*, Dorpat, v. 1890), who finds that they are violent poisons, though acting slowly, especially when given subcutaneously, small toxic doses producing death almost as rapidly as larger ones. In the lower animals, 1 milligramme of the oxide per kilogramme will produce an intense parenchymatous nephritis, followed by violent inflammation of the intestines. There is marked elevation of the blood pressure and widespread degeneration of the tissues, especially of the blood vessels. In mild cases of poisoning a transient glycosuria is a primary symptom.

Uranium calcium phosphate, according to Churchward (*L. L.*, 1911, i, p. 660), is radioactive and may be used instead of radium in the treatment of *rodent ulcers*.

Jackson (*A. J. Phys.*, 1910, xxvi, p. 381) finds that *sodium-uranium tartrate* causes a slight rise in the blood pressure and some increase in the respiration; it destroys the coagulability of the blood, but does not affect its oxygen carrying power.

Urasol. *Acetyl-methylene-disalicylic Acid. Afsal.* $CH_2(C_6H_3{<}^{OC_2H_3O}_{COOH})_2$.—This substance is said to be formed from about 75 per cent. of salicylic acid, 16 per cent. of acetic acid, and 8 per cent. of formaldehyde. It occurs as a yellowish-white powder, insoluble in water, soluble in ether and alcohol, and is incompatible with acids and with iron compounds It has been used in *doses* of five to eight grains (0.32–0.5 Gm.), given in capsules, in *muscular rheumatism*, irregular *gout*, and as an antiseptic in *cystitis* and other inflammations of the genito-urinary tract.

Urea. *N. N. R.* 1914. *Carbamide. Urée*, Fr. *Harnstoff*, G. $CO(NH_2)_2$.—For an account of the physical and chemical properties of *urea*, the reader is referred to treatises upon physiology. Urea has been employed in practical medicine as a hydragogue diuretic in the treatment of *dropsies* and as a tonic alterative in *phthisis*. (*L. L.*, December, 1901.) *Dose*, ten grains (0.65 Gm.) every six hours; increase *pro re nata*. Urea is incompatible with chloral hydrate and lead acetate.

A new and convenient method of determining urea has been found in an enzyme called *urease*, which exists in the soy bean as well as in other leguminous seeds. It readily converts urea into ammonium carbonate by the following hydrolytic reaction:

$$CO{<}^{NH_2}_{NH_2} + 2H_2O = CO{<}^{ONH_4}_{ONH_4}$$

In its use for the quantitative determination of urea the natural alkalinity of the urine must first be determined, which is then compared with the alkalinity of a specimen of the urine which has been treated with the enzyme.

Thio-urea is a substance in which one atom of oxygen in a molecule of urea is replaced by an atom of sulphur, $CS\langle^{NH_2}_{NH_2}$ or C_4N_2S. According to Paul Binet (*Rev. Méd. de la Suisse Rom.*, 1893), it is a very active poison, paralyzing the nerve centers, but leaving intact the peripheral nerves and the muscles. It is used commercially as a photo fixing agent and to remove stains from negatives.

Ureabromine. *Bromo-calcium Urea.* $CaBr_2.4CO(NH_2)_2$.—This occurs as colorless, odorless crystals, freely soluble in both water and alcohol, with a melting point of 186° C. (366.8° F.) and representing 36 per cent. of bromine. It is incompatible with chloral hydrate, potassium iodide and acids. It has been used by Fischer and Hoppe (*B. K. W.*, 1911) with asserted remarkable results in spasmodic conditions of children, especially in *epilepsy*. He attributes this effect not only to the bromine, but also to the readily absorbable calcium it contains. The *dose* for the adult is from thirty to sixty grains (2–4 Gm.).

Urechites. *Urechites suberecta* Jacq. *Savannah Flower. Yellow-flowered Nightshade.*—This is an apocynaceous plant, which grows abundantly in the West Indian Islands and to some extent in Florida, is said to be used in Jamaica by the negroes as a poison. The symptoms which it produces are violent vomiting and purging, with convulsions. J. J. Bowrey (*J. Chem. S.*, June, 1878) has isolated from it two glucosides, *urechitin* and *urechitoxin*, having respectively the formula $C_{28}H_{42}O_8$ and $C_{13}H_{20}O_5$. Isaac Ott (*T. G.*, 1880) finds the plant to be a powerful cardiac poison, first increasing and then depressing the arterial pressure, and finally, if the dose be large enough, killing by producing cardiac arrest. The results reached by Ott are in accord with those of Ralph Stockman (*Laborat. Rep., Royal College of Physicians*, Edinburgh, vol. iv, 1892), who finds that both of the glucosides are very active poisons belonging to the digitalis group. On the other hand, Vowinkie came to the conclusion that even small doses of the plant depress the heart, and experiments made upon man by Bowrey show that in large doses the drug produces nausea, vomiting, general depression, great perspiration, and slight swelling of the pulse. Stockman (*Rev. de Clin. et de Thér.*, June 29, 1892) found that the leaves contain a toxic alkaloid, which he calls *urechitine*, $C_{28}H_{42}O_8 + H_2O$, and a glucoside, *urechitonin*, which is less toxic. In Jamaica the drug is said to have been used in the treatment of *intermittent* and other *sthenic fevers*. The *dose* of the fluidextract is from two to ten minims (0.12–0.6 mils).

Urobiline. *Hydrobilirubin.* $C_{32}H_{40}O_7N_4$.—This biliary pigment, prepared from urine, occurs as a brown resinous mass soluble in alcohol, ether, chloroform, and alkaline solution. It has been proposed by Th. Roman and G. Delluc as a reagent for zinc. A few drops of a solution of urobiline in chloroform, 2 mils of which are mixed with 5 mils of absolute alcohol, will cause a green fluorescence in an alkaline solution containing zinc. (See also *D. M. W.*, 1913, No. 10.)

Urol. *Urea Quinate.* $C_7H_{12}O_{6\cdot2}[CO(NH_2)_2]$.—A chemical combination of one molecule of quinic acid and two molecules of *urea*. It forms very soluble, colorless prismatic crystals fusing at 106° to 107° C. (221.8°–224.6° F.). It is employed in the treatment of *gout, gravel* and *uric acid diathesis* in *doses* of thirty to forty-five grains (2–3 Gm.). This amount is to be dissolved in warm water and taken either on rising or when retiring. It is incompatible with acids.

Ursal.—A compound of urea and salicylic acid, used as a substitute for sodium salicylate.

Urtica. *Ortie brûlante*, Fr. *Brennessel*, G.—Various species of this genus (Fam. *Urticaceæ*) are furnished with poisonous stinging hairs. *Urtica gigas* A.Cunn. (now *Laportea gigas* Wedd.), of Eastern Australia is said frequently to kill horses, and to produce in man a sting whose impression lasts for months. (*N. R.*, 1875.) It has generally been thought that the virulence of the hairs is due to the presence of free formic acid (*A. J. P.*, xxii), and David Hooper (*P. J.*, April, 1887) has demonstrated the presence of formic acid, or a substance very closely allied to it, in the hairs of the *Nilgri nettle* (*Girardinia palmata* Gaudich.). Nevertheless, it does not seem probable that formic acid is the poison. G. Haberlandt believes it to be a non-volatile albuminoid, and L. Reuter has obtained from several nettles a glucoside. (*A. J. P.*, Jan., 1890.) Oddi and Lomonaco (*Rif. Med.*, April, 1892) isolated from the common nettle a crystalline alkaloid, and found that in mammals the extract acts powerfully upon the vasomotor system, and in frogs causes centric paralysis with diastolic cardiac arrest.

U. dioica L., or *common nettle*, and *U. urens* L., or *dwarf nettle*, European plants naturalized in waste places to some extent in the United States, have been used in medicine as local irritants, as diuretics (*A. J. P.*, 1866), and especially for the purpose of arresting *uterine hemorrhage*. The fluidextract may be given in *doses* of half a fluidrachm (1.8 mils) or a decoction of the strength of an ounce to a pint in teacupful doses. Under the name of *brandol* is marketed a preparation used in the treatment of *burns* and *wounds;* it is a liquid consisting of 93 per cent. infusion of urtica, 2 per cent. picric acid and 5 per cent. glycerin.

Ustilago. *U. S.* 1880. *Corn Smut.*—The genus *Ustilago* belongs to the *Ustilaginaceæ*, all the members of which generally develop their spores in the ovary or anthers of the host plant, forming a slimy mass, which in maturing becomes a black dust made up of spores. They produce the *smut* in cereals. *Ustilago Maydis* (DC.) Tul. is produced on the stems, the pistils (corn grains), and the male inflorescence (tassel) of the Indian corn. It is specifically characterized by its minute spherical spores, about 0.007 mm. in diameter. It is abundant in the United States. Upon the corn the smut appears in masses, varying in size from a cherry to a child's head. These masses are smooth, irregularly globose, or sometimes lobulated, having at first a livid, bluish tint, and then becoming blackish, and finally bursting and emitting the black contents, consisting of innumerable globose very minute spores, each of which is covered with beautiful little pointed processes. In a dried state the masses are blackish and covered with a black powder.

C. H. Cressler found in ustilago an alleged alkaloid, *secaline* (*trimethylamine*), besides a thick, viscid, fixed oil and a resin soluble in ether, but not in alcohol. (*A. J. P.*, 1861, 306.) Rademaker and Fischer (*Nat. Drug.*, 1887, 296) believed that

they had discovered a white, bitter alkaloid, *ustilagine*, soluble in ether, while H. B. Parsons decided that the fixed oil contained an acid which he provisionally named *sclerotic acid;* also an amine-like volatile substance extracted by ether. (*N. R.*, March, 1882; also *West. Drug.*, 1894.) A. W. Balch (*Journ. Boston Soc. Med. Sci.*, March, 1901) was not able to find any active substance in the smut.

The belief that corn smut is an abortifacient to the lower animals (*A. J. P.*, Sept., 1861) appears to be without foundation, as in the experiments made by the United States Department of Agriculture in 1898 (*Farmers' Bulletin*, No. 69) no effect was produced by corn smut given to pregnant cows. The experiments of James Mitchell (*T. G.*, ii, 223) that ustilago abolishes sensation, reflex action, and later general motor power in the frog, is contradicted by the results of Balch, who also found that enormous doses of the substance have no effect upon the color of the cock's comb. In *doses* of one to two drachms (3.9–7.7 Gm.) it has been claimed by W. A. N. Dorland that the fluidextract markedly increases the severity and frequency of the uterine pains in human labor. The whole drift of our present evidence is to show that ustilago is probably inert.

Uzara. *Uzaron.*—Under this name the root of an undetermined African plant, probably belonging to the *Asclepiadaceæ*, has been used both by the natives and European physicians in the treatment of *dysentery*, especially of the amœbic variety. Guerber and Frey (*A. E. P. P.*, 1913, lxxv, p. 75) have determined that it contains neither alkaloid nor tannin, but does contain non-nitrogenous glucosides which have a digitalis-like action upon the heart and diminish peristalsis of the intestines. It appears to owe its virtues in part to its amœbicidal action, but in part also to its effect upon the intestinal muscles.

Vaccines. *Bacterins.*—Efficient vaccine therapy is much older than serum therapy. The word vaccine takes its origin from the Latin *vacca*, cow, and Jenner's publication of 1798, "*An Inquiry into the Causes and Effects of Variola Vaccinae.*" (See Part I, *Virus Vaccinicum*, U. S. *Vaccine Virus*, p. 1203.) Vaccination against smallpox is still our most reliable method of immunization against an infectious disease. Pasteur later applied the term vaccine to his attenuated anthrax virus, and Sir Almroth Wright has still further extended it in his "*bacterial vaccines*" to cover killed cultures of micro-organisms injected into man for the cure as well as the prevention of disease. Strictly, vaccine should mean only one thing, the virus of vaccinia or cow pox.

The various products treated below have this in common, that they are disease producers so modified as to be comparatively harmless, and are used to immunize against the disease which in their virulent form they cause.

This immunization may be either to prevent infection or to ameliorate, or cure, an already existing infection. Vaccines, then, are classed as *antigens*, while serums represent *antibodies*. In receiving a vaccine, the patient is called upon to manufacture his own antibodies. This fact is not to be lost sight of, particularly in serious illness. By vaccine treatment there is being introduced into the body material more or less similar to those invaders which the body forces are already striving to overcome. The balance in the struggle may be a narrow one, and such a load, though well intended, may turn the battle in the wrong direction. On the other hand, for preventive immunization, vaccine therapy has the advantage that the antibodies produced in the patient's own serum are more stable than when introduced in foreign serum and, furthermore, that the cells of the body as well as the blood fluid may be brought into the defensive line.

The greater part of these vaccines are bacterial vaccines. These are suspensions of killed bacteria in physiological saline solution, with 0.25 to 0.5 per cent. phenol or cresol as preservative. The bacteria are grown on a solid medium, such as agar, are washed off with the saline solution, and the killing is usually accomplished by heating one hour at 53° to 60° C. (127.4°–140° F.), though strong antiseptics may be used for this purpose.

The number of organisms per mil is estimated by direct counting in a microscopic chamber, by comparison with the number of blood cells in normal human blood, or by relative density; saline solution is then added to reduce the suspension to the desired strength. When in the final containers tests are made to insure sterility.

"*Stock vaccines*" are prepared from strains of the different organisms carried in stock by the producer. "*Autogenous vaccines*" are made up from the actual cultures obtained from the patient to be treated and are usually preferred (see remarks on specificity, under *Immune Serum*, p. 1603). Nevertheless, on account of the delay and expense of obtaining and isolating the patient's own strain, stock vaccines are often used. For prophylactic immunization, of course, stock vaccines are necessary.

Aside from prophylaxis (*typhoid fever, cholera*) the success in bacterial vaccine therapy seems to have been attained in chronic, sluggish, localized infections.

Bacterial vaccines deteriorate with age—how much we are unable to tell until we have a measure of their potency. They should, however, be kept at 4° to 15° C. (39°–59° F.) and be used within a short time—probably three or four months—of their preparation.

Rabies Vaccine. N. N. R. 1917. *Antirabic Virus. Pasteur Treatment.*—The prevention of *hydrophobia* in persons bitten by rabid animals is one of the debts owed by the world to Pasteur. While formerly 15 per cent. of such unfortunate people contracted rabies and died, the mortality now in treated cases is less than 1 per cent. usually and in some institutes almost zero. The treatment is in a sense a preventive one. It is instituted after the bite, but before symptoms have developed. On account of the long incubation period in rabies there is then opportunity to acquire immunity in most cases.

The dried cord method of Pasteur, which is still the most used on account of its long successful history, consists in daily hypodermic injections of portions of the dried spinal cord of rabid rabbits.

The rabbits have been inoculated intradurally with "fixed virus," that is, a virus whose incubation period has been shortened and fixed at five to seven days by passage from rabbit to rabbit through a long series. The usual incubation period of "street virus," or rabies as it occurs naturally, is from 12 to 90 days. In this process of fixation the virus gradually loses its virulence for man. The cords of the rabbits are dried for various lengths of time over caustic potash in an aseptic manner; if dried for 6 days, the cord is

called a "6-day cord." The treatment is begun with cords dried the longest time; originally Pasteur began with a 14-day cord, but the tendency has been to use cords dried fewer and fewer days, as the fixed virus has been found practically innocuous for man. The treatment lasts about 21 days, a piece of cord 5 millimeters long is emulsified in 2.5 mils salt solution and injected each time. Other modifications of the Pasteur treatment are the injection of weak dilutions of the fresh fixed virus (Högyes), the carbolization of the virus (Fermi), attenuation by dialysis (Cumming) or by drying while frozen (Harris). The virus should be prepared as few hours as possible before its use.

Acne Bacillus Vaccine. *N. N. R.* 1917.—The acne bacillus is a short rod, not decolorized by Gram's stain, growing only in the absence of oxygen, and even sluggishly then. The vaccine prepared from it is used in cases of *acne* in which the bacillus is found and which do not improve under the usual staphylococcus vaccine. The usual *dose* is about 5,000,000 killed bacteria.

Cholera Vaccine. *N. N. R.* 1917.—The cholera vibrio is the cause of *Asiatic cholera.* It is a curved rod, decolorized by Gram's stain, a rapid grower, and prefers an alkaline medium. The vaccine is used prophylactically with good success in Japan. The following results with the vaccine are reported by the Japanese Imperial Institute:

	Case rate per 100,000	Case mortality rate per cent.
Inoculated	55	39.5 per cent.
Uninoculated	70	74.5 per cent.

Gonococcus Vaccine. *N. N. R.* 1917.—The gonococcus is a thick, coffee-bean shaped organism occurring in pairs. It is decolorized by Gram's stain and is difficult to grow, even on media which contain one of the body fluids. In *gonorrheal urethritis, vaginitis,* and *ophthalmia* no benefit is to be expected from vaccine treatment. Some favorable influence is frequently exercised by the vaccine in cases of *gonorrheal arthritis.* The *doses* used are 5,000,000 (freshly isolated cultures) to 1,000,000,000 (old strains).

Pertussis Bacillus Vaccine. *N. N. R.* 1917.—The pertussis bacillus, or bacillus of Bordet-Gengou, is the cause of *whooping-cough.* It is a very small Gram-negative rod, growing at first only on special media. The vaccine prepared from this organism is used both as a preventive and in the treatment of whooping-cough. In the former case three doses of 50,000,000 to 2,000,000,000 are given a week apart. For treatment, the *doses* range from 50,000,000 to 2,000,000,000 every two to four days. It is reported that the vaccine treatment makes the attack milder and in particular shortens the course of the disease.

Plague Bacillus Vaccine. *N. N. R.* 1917. *Haffkine Prophylactic.*—The bacillus of *bubonic plague,* or *Bacillus pestis,* is a short, Gram-negative rod which has a tendency to take up the stain more intensely at the ends, leaving a relatively light staining central portion. It grows fairly well on ordinary laboratory media and is one of the most virulent bacteria known, since it will easily cause a fatal infection by mere contact with the abraded skin. The vaccine is used with fair success as a preventive—those inoculated being less prone to the disease than the uninoculated in the same community and having relatively milder attacks if not entirely protected. Though the prophylactic is useful for travelers through badly infected territory, reliance in a plague outbreak is to be placed in eradicative measures rather than in Haffkinization of the population.

Staphylococcus Vaccines. *N. N. R.* 1917.—There are three species or varieties of staphylococci concerned in human disease, the *Staphylococcus albus,* which produces a white growth on solid media; the *Staphylococcus aureus,* which produces golden yellow, and the *Staphylococcus citreus,* giving a lemon yellow. The first of these is the usual cause of the relatively mild skin pimples and boils; the second is more likely to be encountered in more severe abscesses and carbuncles, while the third is relatively rare. All are large round organisms, Gram positive and tending to a tessellated arrangement; rapid growth is obtained on all ordinary media. It is with these organisms that the most striking successes of vaccine therapy have been made, particularly in *furunculosis.* If possible, the vaccine should be autogenous, but cure is frequent with stock vaccines. Some cases will not respond even to autogenous vaccines. The initial *dose* is usually 20,000,000 to 100,000,000, repeating with an increase every four or five days until a slight reaction is obtained, then proceeding more slowly until a cure is effected. As with other methods of treating this affection, relapses are not infrequent; more intensive and prolonged treatment is then indicated. *Sycosis vulgaris, pustular acne, carbuncles, abscesses* are all amenable to vaccine therapy to a greater or less degree, but, especially in the two latter, surgical measures should not be neglected.

Streptococcus Vaccine.—There is difference of opinion regarding the unity or the plurality of the disease producing types of streptococci. The usual *Streptococcus pyogenes* is a round or oval organism. Gram positive, tending to be arranged in chains, and to divide with the line of division at right angles with the chain; the cocci often appear in pairs. This organism grows less readily and in smaller colonies than the staphylococcus. The streptococci forming long chains (*Streptococcus longus*) are thought to be more pathogenic than those with short chains (*Streptococcus brevis*). On blood agar the colonies have a clear halo, due to hemolysis (*Streptococcus hemolyticus*). Other strains (called *Streptococcus viridans*) produce greenish colonies under like conditions; these latter are found in infections such as *endocarditis* and *arthritis,* while the hemolytic strains occur in the virulent, pyogenic *phlegmons* and fatal *septicemias.* Another form, *Streptococcus mucosus,* produces a mucoid growth, and has a capsule like the pneumococcus.

The name *Streptococcus rheumaticus* is given to the streptococci found in *rheumatism, Streptococcus erysipelatus* to those of *erysipelas,* and some suppose a particular streptococcus to be the causative agent in *scarlet fever.* The evidence for the latter is poor, the streptococci found in this disease and responsible for the greater number of the complications being probably secondary invaders.

On account of our inability to treat the greater part of the streptococcal infections directly, this has been a favorite field for vaccine therapy, but the results are far from convincing. Russian reports of successful prophylaxis of scarlet fever by the use of streptococcus vaccine have not been confirmed in this country. Occasional favorable results are obtained in the treatment of one or another conditions of streptococcal invasions, espe-

cially if attention is paid to strain specificity and the tendency of the organisms to decrease in pathogenicity and immunizing power under artificial cultivation.

Streptococcus and Prodigiosus Vaccine. N. N. R. 1917. *Toxins of Erysipelas and Prodigiosus. Coley's Fluid.*—This suspension, used in the treatment of inoperable *sarcoma*, is practically a bacterial vaccine prepared from *Streptococcus pyogenes* and *Bacillus prodigiosus*. Due to the latter, the fluid has a reddish tint. An analysis of the reported cases in which it has been used indicates that it is probably of some value in the field for which it is recommended.

Typhoid Bacillus Vaccine. N. N. R. 1917. *Typhoid Vaccine. Typhoid Prophylactic.*—The typhoid bacillus, or *bacillus of Eberth*, is an actively motile rod, sometimes very short, sometimes by the end-to-end arrangement of several individuals, long and filamentous, Gram-negative and growing readily on ordinary media. It is the cause of *typhoid fever*—in German *typhus*, but to be distinguished from true typhus fever, or *typhus exanthematicus*. As the staphylococcus vaccines are the best examples of vaccine therapy, so typhoid vaccine is the best example of prophylaxis by bacterial vaccine. Treatment of *typhoid fever* by vaccines, while yielding some slightly encouraging results, is often dangerous on account of the severity of the general infection. Attempts to rid typhoid carriers of their bacilli by vaccine therapy are occasionally successful, usually not.

In 1896 Pfeiffer and Kolle in Germany and Wright in England began work on typhoid immunization. The German vaccine was grown on solid medium-agar—the English in broth and heated to 60° C. (140° F.). Later Leishman found that heating to 53° to 54° C. (127.4°–129.2° F.) was sufficient and gave better immunization. The English used one injection at first, then two, eight days apart. Kolle advised three. The method of the American army, instituted by Russell, followed the agar cultures and the triple dose of Kolle, but used Leishman's strain and temperature. The results in the United States Army are well known and striking; together with improved sanitation, the compulsory vaccination has practically eliminated typhoid. In the 1898 camp at Jacksonville, before vaccine protection, there were 10,759 troops and 248 deaths from typhoid. In the camp at San Antonio covering a similar period in 1911, after vaccination, there were 12,801 troops and no deaths from typhoid.

The vaccine is a suspension containing one billion bacilli per mil. The injections are given seven to ten days apart, the first being one-half mil, the second and third one mil, hypodermically. Reactions both local and febrile are often seen within forty-eight hours, more frequently with some lots of vaccine than with others. It appears that the intensity of reaction given by a given lot of vaccine may bear some relation to its immunizing power. The vaccine produces agglutinines (positive Widal test) in men and animals injected, also bacteriotropism or opsonin against the typhoid bacillus. Typhoid vaccine probably becomes more or less inactive after a few months and should be kept at a temperature between 4° and 15° C. (39.2°–59° F.) in the dark.

The protection given by the vaccine is not absolute nor life-long, but for three years it is usually sufficient to resist all ordinary intensities of infection, and some immunity doubtless persists through life. Even when the vaccinated do chance to contract the disease, their attack is generally much milder than in the unvaccinated.

There have been combined with the typhoid vaccines in some instances vaccines against infection with *paratyphoid bacillus A* and *paratyphoid bacillus B*. These two infections, though generally milder, resemble typhoid in their symptoms and in the types of causative organism. It appears that immunization against all three diseases can go on simultaneously.

Pollen Extract. N. N. R. 1917. *Hay Fever Vaccine.*—This product is included with the vaccines because it depends on an immunological response on the part of the person receiving treatment. Hay fever and rose cold are probably caused by the irritant action of the pollen of certain plants on the ocular and respiratory mucous membranes of especially sensitive individuals. By skin inoculation it is often possible to determine to what pollens a person is sensitive. The administration of pollen extract is an attempt to decrease their sensitiveness, in other words, to immunize the patient against the pollen. The Gramineæ or grasses are chiefly concerned in the production of rose cold (June cold), and the Compositæ in that of *Hay fever* or autumnal catarrh. Pollen extracts have been prepared from each of these two great classes and favorable reports from treatment are not uncommon. The extract is usually given in a long series of injections, preferably before the symptoms of the year appear. The extract is unstable and should be used when freshly prepared. Severe reactions may also occur with potent extract unless the symptoms are watched and the increase in dosage made gradually.

Vaccinium. *Vaccinium crassifolium* Andr. (Fam. *Vacciniaceæ.*)—The leaves of this American shrub are said to be astringent and diuretic, and capable of replacing uva ursi. *Dose*, of the fluidextract, from a half to one fluidrachm (1.8–3.75 mils).

Valamin. *Iso-valerianic-ester of Amylene Hydrate.* $(CH_3)_2C_2H_5.COOC_5H_9$.—It occurs as a colorless liquid sparingly soluble in water with a taste and odor suggesting that of valeric acid. It is used as a nerve sedative and mild hypnotic in *doses* of from four to fifteen grains (0.25–1 Gm.).

Valeric Acid. *Valerianic Acid. Acidum Valericum. Acidum Valerianicum. Isopropylacetic Acid.* $HC_5H_9O_2$. Mol. wt., 102.08. *Acide valérianique, Acide valérique*, Fr. *Valeriansäure, Baldriansäure*, G. *Acido valerianico, It.*, Sp.

In the 1860 U. S. revision this acid was transferred from the Preparations to the Materia Medica list; in that of 1880 it was dropped entirely.

For modes of preparing valeric acid from the oil and roots of valerian, the reader is referred to the article on Valerian in this work, and for other methods of producing valeric acid, see *U. S. D.*, 19th ed., p. 1688. It is prepared also from amyl alcohol by reaction with a mixture of potassium dichromate and sulphuric acid, as the first step in the preparation of sodium valerate.

Valeric acid (originally valerianic acid) received its name from having been found in the oil distilled from the root of *Valeriana officinalis* L. (Fam. *Valerianaceæ*). It was first obtained in 1817 by Chevreul from the oil of the dolphin, and received the name of *delphinic acid*, which, however, upon the discovery of its identity with the acid afterwards obtained by Pentz from valerian, was superseded by its present title. It has been

obtained also from the bark and fruit of *Viburnum Opulus* L. and other species of *Viburnum* (Fam. *Caprifoliaceæ*), the sap wood of the European elder (*Sambucus nigra* L.) (Fam. *Caprifoliaceæ*), the root of *Angelica Archangelica* L. (*Archangelica officinalis* Hoffm.) (Fam. *Umbelliferæ*), and from various organic products of the vegetable and animal kingdom.

Valeric acid is a colorless liquid, of an oily consistence, a repulsive odor, resembling, however, that of valerian, and a pungent, sour, acrid, disagreeable taste. Its sp. gr. is 0.937 for the synthetic acid and 0.931 for the natural. It is soluble in thirty parts of cold water, and when agitated with water takes up about 20 per cent., without losing its oily consistence, and rises to the surface of the liquid. Alcohol and ether mix with it in all proportions. It is very soluble in strong acetic acid and dissolves camphor and some resins. It forms salts with the alkalies and reddens litmus paper strongly, but the blue color gradually returns in a warm place. For tests of purity by Mossler, see *P. J.*, 1911, 175.

The virtues of valerian have been attributed to valeric acid and the latter has therefore been used as a nerve sedative, but it is probably inert. The customary *dose* is from three to ten minims (0.2–0.6 mil).

Valeridin. *Valerydin. Sedatin. Iso-valeryl-p-phenetidin.* $C_6H_4\begin{cases}NHCOC_4H_9\\OC_2H_5\end{cases}$.—This substance occurs as white, glistening needles, which are readily soluble in alcohol or chloroform, difficultly soluble in ether, and almost insoluble in water. It is obtained by heating isovaleric acid with p-phenetidin. C. Erdmann (*Ph. Ztg.*, xliii) commends this substance in *doses* of from eight to fifteen grains (0.5–1.0 Gm.) a day, as a succedaneum for valeric acid, and as being very serviceable in *migraine, neuralgia* and *hysteria.*

Validol. *N. N. R.* 1917. *Menthyl Valerate.* $CH_3.CH_2.CH_2.COO.(C_{10}H_{19})$.—*Validol* is a clear, colorless liquid, of a mild, pleasant odor, and slightly bitter taste, said to contain 30 per cent. of menthol combined chemically with 70 per cent. of valeric acid. It was originally proposed by Schwersenski (*Th. M.*, 1897) as being locally nonirritant and affording a means of exhibiting menthol; for its local action in *pruritus, gastralgia, coryza,* various mucous inflammations, and as an antispasmodic in *migraine, neurasthenia, hysteria* and other neuroses. Validol has also been used as an antiemetic, for the relief of *sea-sickness* and in other forms of *nausea.* It is stated to be specially eliminated through the urine, to which it imparts a peculiar odor. *Dose,* five to twenty minims (0.3–1.3 mils); locally 10 to 15 per cent. ointment is recommended.

Validolum Camphoratum is a 10 per cent. solution of camphor in validol.

Valofin.—This is stated to be a combination of peppermint extract with *valeryl ethylate* and ammonium valerate. It has an agreeable odor and is so concentrated that a teaspoonful when mixed with a cupful of warm water will represent an infusion of peppermint and valerian. It is used as a nerve sedative in *doses* of from fifteen to thirty minims (1–2 mils).

Valonia. *Acorn Cups. Valloné, Vélanède, Gallon,* Fr. *Knoppern, Walonen,* G.—The great cups of the acorns of the *Quercus Aegilops* L. (Fam. *Cupuliferæ*), a native of Bosnia, contain a very large percentage of tannin. They are extensively exported for dyeing and tanning, and have been employed as an astringent in *diarrhea.*

Valyl. *N. N. R.* 1917. *Valeric Acid Diethylamide.* $C_4H_9.CO.N(C_2H_5)_2$.—It occurs as a colorless liquid having a characteristic odor and burning taste, and boiling at 210° C. (410° F.). According to Kionka (*D. M. W.*, xxvii, 1901), valyl produces cerebral excitement, attended with convulsions, probably of cerebral origin, as there is no increased reflex activity. It is said primarily to increase the blood pressure and to have little action upon the heart or respiration. It is somewhat irritant, but may be given in four per cent. aqueous solution, and has been used as a substitute for valerian in *hysterical* and allied *neuroses. Dose,* four to fifteen grains (0.26–1.0 Gm.) three times a day, preferably administered with an equal amount of tallow in gelatin capsules.

Vanadic Acid. *Acidum Vanadicum.* (*Meta-vanadic Acid,* HVO_3.)—Forms golden-yellow scales, which are only slightly soluble. According to Le Blond and C. David, *vanadic acid* is actively antiseptic, and very useful in solutions for the skin, 0.05 in 1000; for gynecological use, 0.17 in 1000.

Sodii Vanadas. Sodium Vanadate. $NaVO_3$. This is a yellowish-white powder, freely soluble in hot water.

Ferri Vanadas. Iron Meta Vanadate. $Fe_3(VO_3)_6$.—A dark, grayish-brown powder, almost insoluble in water.

Lithii Vanadas. Lithium Meta Vanadate. $LiVO_3 + H_2O$.—A yellowish-white crystalline powder, freely soluble in water.

The meta vanadates are used in preference to the ortho, pyro, etc., due to their stability in solutions. They are incompatible with acids, the latter imparting to their solutions a yellowish-red color.

In the arts vanadic acid is used in various oxidizing processes as a carrier of oxygen, effecting by its presence the more efficient action of other oxidants, as in the aniline black formation, where a small amount of ammonium vanadate is capable of taking the place of large amounts of chlorates and similar oxidizing agents. It is also used in vanadium inks.

According to Jackson (*J. P. Ex. T.*, 1912, iv, p. 1) sodium orthovanadate, when injected in large doses, produces a slight rise in the general blood pressure, which is due to constriction of the vessels of the abdominal region, increased peristalsis of the intestinal tract, salivation, vomiting and diarrhea, more or less spasm of the bronchial muscles, and death from respiratory failure.

According to Dutton (*J. A. M. A.*, June 3, 1911), workers in industries in which vanadium is used, suffer from a form of *chronic poisoning,* the most important results of which are congestion of the lungs and of the kidneys, and sometimes *hemorrhagic nephritis* and also irritation of the gastro-intestinal tract. *Anemia* is an early symptom, and there is usually a dry cough, loss of appetite, emancipation and albuminuria.

The vanadates have been used in *anemia, tuberculosis* and a host of other chronic diseases, but are probably without therapeutic virtue. The usual *dose* of sodium or lithium meta vanadate is from one-sixtieth to one-fifteenth of a grain (0.001–0.004 Gm.).

Under various names, as *vanadiol, oxylasine,* etc., various proprietary preparations containing vanadium have been introduced for which extraordinary therapeutic properties were claimed. The

evidence in support of these claims, however, is extremely unsatisfactory.

Vandellia. *Vandellia diffusa* L. (Fam. *Scrophulariaceæ.*)—This is an herb of Paraguay, said to be used by the natives as an emetic. (*P. J.*, 1872, 849.)

Vanilla. *N. F. IV* (*U. S. P. VIII*). *Vanilla Bean. Vanille,* Fr. Cod. *Fructus Vanillæ,* P. G. *Vanille,* G.—"The cured, full-grown, unripe fruit of *Vanilla planifolia* Andrews (Fam. *Orchidaceæ*)." *N. F.*

Vanilla planifolia is a fleshy, dark green, perennial climbing plant, with a very long, smooth, dark green stem, much branched, and furnished at the nodes with aerial roots, which cling to the tree or the wooden framework supporting the plant. The dark green, tough leaves are alternate, oval, sessile, attenuate at the apex, fleshy and veinless. The pale greenish-yellow, sessile flowers are about two inches in diameter, and occur in loose, axillary racemes of eight or ten. The fruit is a slender pod, seven or eight inches long, filled with an oily mass containing numerous small, black, shining seeds.

This plant is a native of the West Indies, Mexico and South America, but is now extensively cultivated. The plant does well from the sea-level up to two thousand feet of altitude, requiring for its perfection, however, a moist, hot climate, with an habitual dry summer spell which seems to be necessary to bring good flowering. It is propagated by means of cuttings, sometimes two or three feet in length, but preferably from ten to twelve feet long, taken from growing shoots; these are planted after the dry season is over and should produce flowers in two years. Preferably placed upon trees, but sometimes on long stakes, trellises, wire supports, etc., the slip is placed with one end on the ground, covered with leaves or some light top dressing. In many cases the vines are planted so closely as scarcely to leave room for cultivators to pass, but it has been found that under these circumstances the vanilleries are especially liable to destructive fungous diseases. As the flower does not fertilize itself, fertilization (pollination) by hand is necessary; it is usually performed by women and children. It is said that a fairly trained workman can fecundate over one hundred flowers per hour. In most localities not more than thirty fertilized flowers should be left to a plant. The pods reach their full size in from five weeks to eight months, according to the altitude of the locality and to the amount of shade. The first indication of ripening is a slight yellowing of the whole pod; as soon as this occurs the pods should be picked, and sorted, and the curing process commenced. If left to ripen further the pods are prone to split and otherwise deteriorate. For the purpose of curing them the pods are kept in a heated room for some days (about 110° F.), then transferred to a cooler one (90° F.), and finished at ordinary temperature. During the process, which lasts some months, there is a loss of 70 to 80 per cent. of weight. For details as to culture, see *Bulletin* 21, 1898, U. S. Department of Agriculture, Division of Botany. The practice of curing the beans by placing them under blankets in the sun is still in vogue, but that of using a regulated artificial heat is more certain, and it is the modern method.

When thoroughly cured the beans are sorted and tied into bundles, which are wrapped in sheet lead or placed in small metallic boxes. In doing this it is essential that the bundle be wrapped in a thin vegetable parchment paper, as chemical action occurs when the beans come in contact with the metal.

Fruits which have not been picked early enough are inferior and are frequently cut into short pieces and sold as "cuts." If by chance the fruit should be picked too early the quality of the resulting product is distinctly inferior. The fruit as first picked has no aroma, the *vanillin* during the process of curing being produced from the glucoside *coniferin* in the interior of the fruit. This was shown to be converted into *coniferyl alcohol* and glucose, and the former of these subsequently changed into vanillin.

The cultivation of vanilla has extended from South America throughout the tropics, so that at present, although the wild plant is abundant in the Mexican States of Vera Cruz and Oaxaca the vanilla of the markets comes almost exclusively from vanilleries. Holland is supplied from Java plantations; France from Tahiti, Madagascar, Réunion, Guadeloupe, and other of her colonies. From Mauritius and the Seychelles the product goes to London. In the markets most of the varieties are known by the name of the country in which they are produced. The finest of the varieties is the Mexican, although of recent years the Bourbon beans have so improved that they almost rival it in strength and flavor. At present the Mexican bean is sold at somewhat less than double the price of the Bourbon; the Bourbon at almost double the price of the Tahiti, the latter bean being commonly much injured by carelessness in the process of curing.

Of *Mexican vanilla,* the first quality occurs in pods from 15 to 20 cm., long, flattened, 6 to 8 mm. in diameter, with the lower end slightly attenuated, the upper end gradually tapering for about a quarter of the length of the pod, usually curved and slightly twisted near the point. The color is dark brown, the pods fairly plump, the surface ridged longitudinally, and with an incrustation of fine crystals beginning at the ends, gradually extending; when fresh somewhat viscid, but always roughish to the touch. For an interesting account of the Mexican vanilla plant by Charles E. Hires, see *A. J. P.*, 1893, 576.

Of the Mexican vanillas the most valuable variety, called *ley,* or *vainilla mansa,* by the Spaniards, consists of cylindrical, somewhat flattened pods, six or eight inches long, three or four lines thick, nearly straight, narrowing towards the extremities, bent at the base, shining and dark brown externally, wrinkled longitudinally, soft and flexible, and containing within their tough shell a soft black pulp, in which numerous minute, black, glossy seeds are embedded. It has a peculiar, strong, agreeable odor, and a warm, aromatic, sweetish taste. The interior pulp portion is most aromatic. In it are more or less numerous, minute crystals. Another variety, called *vainilla simarona* by the Spaniards, is smaller, of a lighter color, and less aromatic. The pods are said to be very dry and to contain no vanillin. (*Nueva Farmacopea Mexicana.*) According to Schiede, it is yielded by a distinct species, the *Vanilla sylvestris* Schiede. A third variety is the *vainilla pompona* of the Spaniards (*boba vainilla,* or *plátano vainilla*). In this, the pods are from 12 to 18 cm. long, from 12 to 18 mm. broad, shaped somewhat like a plantain, almost always open, very dark brown or nearly black, soft, viscid, and of a strong odor. Schiede states that it is the product

of the *Vanilla Pompona* Schiede. The variety *vainilla vezacate* is said to be derived from pods gathered long before maturity. (*Nueva Farmacopea Mexicana.*) The *vainilla pompona* of the Spaniard is evidently the *vanillons* of European commerce, which are usually from 10 to 13 cm. long and from 15 to 25 mm. in diameter, frequently sharply angled, brown to red-brown in color, usually split open and free from efflorescence. Owing to the transverse markings by twine with which they have been wrapped during the process of curing, the beans have a peculiar twisted appearance. Their odor, which resembles that of heliotrope, is due to the presence in them of *heliotropin*, in lieu of *vanillin*.

Bourbon vanilla, produced in the Isle of Réunion to the amount of 200,000 pounds a year, resembles Mexican vanilla, but is scarcely so long in the tapering portions, is of a dark-brown almost black color, is not so firm as the Mexican, has the surface smooth and waxy, and soon becomes covered with a coating of acicular crystals known as "frost." The odor of this vanilla is said to resemble that of Tonka bean rather than that of Mexican vanilla.

The *Seychelles* and *Mauritius vanilla* (*inferior Bourbon* of the trade) has the pods about six inches in length, not over a quarter of an inch in width, and characterized by the pale color, the faint odor, and a smooth but not waxy surface.

South American or *Guadeloupe vanilla* resembles the Mexican bean, but is usually recognizable, when the bean is entire, by the latter being broad and flattened, usually half an inch or more wide, slightly tapering at the lower end, and at the upper sharply attenuated an inch or so at the point. It has a reddish-brown color, and is of a rank odor. It is very pulpy, with a surface intermediate in feel between the Bourbon and the Mexican, and having but few crystals. One variety of this vanilla, sold under the name of *vanillons*, has the odor of heliotrope and is much used by perfumers and tobacco manufacturers.

Tahiti vanilla, "*transplanted Mexican vanilla*," has its pods from six to seven inches long, flat, from three-eighths to half an inch wide, with a reddish-brown color. They are almost destitute of vanilla flavor, and have an odor suggesting heliotrope. It is said they contain piperonal and also vanillin. (*Ph. Cb.*, 45.)

Java vanilla, which is almost exclusively consumed in Holland, has a pod from four to six inches long, with a flavor as fine as that of the Mexican bean, and a much stronger odor.

Vanilla pods are described by the N. F. as: "Pods linear, flattened, from 15 to 35 cm. in length and from 5 to 9 mm. in breadth: summits terminating in flat circular scars; gradually tapering, more or less bent and curved or hooked at the bases, or in the Tahiti variety, broad in the middle and tapering towards either end, the base closely resembling the summit; externally blackish-brown, longitudinally wrinkled, moist-glossy; occasionally with an efflorescence of vanillin in the form of acicular crystals or monoclinic prisms; frequently with narrow, elliptical or irregular, more or less wrinkled, dark-brown patches of cork; occasionally split into three parts near the tip, flexible and tough, one-celled, containing a blackish-brown pulp and numerous blackish-brown seeds; the latter being flattened, irregularly triangulate or nearly circular in outline, reticulate and varying from 0.25 to 0.3 mm. in diameter. Odor and taste characteristic and very agreeable. Under the microscope, transverse sections of the pods of Vanilla show an epidermis with a somewhat thickened outer cuticularized layer having occasionally rounded or conical masses of an excretion of a gum-like substance; a layer of collenchyma of one or two rows of cells; a thick sarcocarp composed of parenchyma cells in which are imbedded an interrupted circle of fibro-vascular bundles; the parenchyma cells are deeply undulate in outline and usually contain a thin protoplasmic layer enclosing numerous oily globules or may contain bundles of raphides of calcium oxalate; the individual crystals varying from 0.2 to 0.4 mm. in length; some of the parenchyma cells are specially modified and distinguished by their somewhat thickened walls with long, oblique, slit-like pores or the thickening may extend in the form of broad, spiral bands; in the fibro-vascular bundles the phloem is central, being more or less surrounded by a few tracheæ, the walls possessing slit-like pores or spiral thickenings, and at the outside of the bundle is a closed circle of sclerenchymatous fibers, the walls being thin, strongly lignified, provided with numerous, transverse, simple pores, the outer wall of the outer row of fibers being irregular or sinuate; from the inner walls of the endocarp arise the placentæ bearing numerous brownish-red or blackish seeds, and from the cells of the endocarp also arise numerous long, nearly straight hairs, the ends being rounded, the hairs being more or less matted together by a gummy or resinous mass in which some of the seeds are held; in mounts made in hydrated chloral T.S. or potassium hydroxide T.S., the immature, brownish-red seeds show a deeply reticulate seed-coat, with cells of an oblong-polygonal form in surface view. Place a few of the crystals, occurring as an efflorescence on the fruit, on a microscope slide or watch crystal and add a drop of phloroglucinol T.S. and hydrochloric acid; the solution immediately acquires a carmine-red color (distinction from *benzoic acid*). The amount of extractive yielded to dilute alcohol should not be less than 12 per cent. Vanilla yields not more than 6 per cent. of ash." *N. F.*

Transverse sections of the pods of vanilla show an epidermis with a somewhat thickened outer cuticularized layer having occasionally rounded or conical masses of an excretion of a gum-like substance; a layer of collenchyma of one or two rows of cells; a thick sarcocarp composed of parenchyma cells in which are imbedded an interrupted circle of fibro-vascular bundles; the parenchyma cells are deeply undulate in outline and usually contain a thin protoplasmic layer enclosing numerous oily globules or may contain bundles of raphides of calcium oxalate; the individual crystals varying from 0.2 to 0.4 mm. in length; some of the parenchyma cells are specially modified and distinguished by their somewhat thickened walls with long, oblique, slit-like pores or the thickening may extend in the form of broad, spiral bands; in the fibro-vascular bundles the phloem is central, being more or less surrounded by a few tracheæ, the walls possessing slit-like pores or spiral thickenings, and at the outside of the bundle is a closed circle of sclerenchymatous fibers, the walls being thin, strongly lignified, provided with numerous, transverse, simple pores, the outer wall of the outer row of fibers being irregular or sinuate; from the inner walls of the endocarp arise the placentæ bearing numerous brownish-red or blackish seeds and from the cells

of the endocarp also arise numerous long, nearly straight hairs, the ends being rounded, the hairs being more or less matted together by a gummy or resinous mass in which some of the seeds are held; in mounts made in hydrated chloral T.S. or potassium hydroxide T.S., the immature, brownish-red seeds show a deeply reticulate seed-coat, with cells of an oblong-polygonal form in surface view.

A characteristic test for the vanillin crystals which occur as an efflorescence on the fruit is as follows: On a microscope slide or watch crystal, place a few crystals and add a drop of phloroglucinol T.S. and hydrochloric acid; the solution immediately acquires a carmine-red color (distinction from *benzoic acid*). The amount of extractive which vanilla of good quality yields to dilute alcohol should not be less than 12 per cent. Nor should it yield more than 6 per cent. of ash.

Vanilla beans from which the vanillin has been removed by means of a solvent are sometimes offered for sale. The fraud is to be detected by the absence of flavor and odor. Such beans, and also beans of an inferior quality, are sometimes "improved" in appearance and in odor by the use of benzoic acid. For the detection of this fraud the pharmacist should avail himself of the fact that while the crystals of benzoic acid are flattened and rhomboidal and generally lie upon the bean, those of vanillin are usually acicular and stand out at right angles from the surface of the fruit. The absence of the crystalline coating on the vanilla beans seems to be no proof of inferiority, for Henri Lecomte affirms that it is not rarely absent in the best Mexican bean. (*B. Sc. Pharm.*, 1901.)

According to Bucholz, vanilla does not yield volatile oil when distilled with water, and the aroma appears to depend on chemical changes which may take place during and after the curing of the fruit. Many years since, vanilla was analyzed by Bucholz and Vogel, the former of whom found in it a disagreeable-smelling fixed oil, a soft resin having a feeble odor of vanilla when heated, a bitterish extractive resembling tannin, sugar, starch and benzoic acid. But the characteristic odorous principle was not isolated until Gobley obtained *vanillin* by acting on vanilla with solvents (see *Vanillinum*). Although the latter substance has been largely manufactured, it does not take the place of the preparations of vanilla, the flavor and odor of the latter being greatly preferred. It passes with water in distillation. If vanilla, finely divided, be distilled with water, a turbid liquid passes, which becomes clear by agitation with ether, and the ether on evaporation yields crystals of vanillin. Vanilla, in the fresh state in which it is gathered, does not in the least possess the characteristic fragrant odor. H. Lecomte (*J. P. C.*, 1903, 343) studied the conditions which bring about the formation of vanillin. According to his researches, there exist in the vanilla plant two ferments, which differ in a marked degree from each other in their functions. The one, an oxydase, is present in the individual organs of the plant, such as the leaves, shoots and their aqueous extracts, in the green and ripe fruit, and in the prepared commercial fruit. Lecomte detected it in the organs of plants of different origin, by means of G. Bertrand's reactions. At the same time, the presence of manganese salts was observed in all products, which renders it not impossible that they stand in some relation to the above-named ferment. The second ferment is contained in the sap of the vanilla, and acts as a hydrolyzing ferment. With regard to the mechanical treatment of vanilla, it would appear in the first instance as if it counteracted the function of the ferment. It consists, as is well known, of the immersion of the fruit during twenty seconds in water at 85° C. (185° F.), a manipulation which might bring about the destruction of the ferment. But the author has convinced himself that a temperature of about 50° C. (122° F.), such as the interior of the fruit probably only reaches during the short duration of the process, really promotes the function of the oxydase. Both ferments, the oxydase as well as the one possessing the hydrolytic action, appear to be necessary for the formation of vanillin in the plant, and their action may possibly be explained thus: During the preparation, the coniferin produced by the plant is split up into glucose and coniferyl alcohol. This process would explain also the occurrence of grape-sugar in vanilla. The oxydase then converts the coniferyl alcohol into vanillin. Tiemann and Haarmann obtained from Mexican vanilla 1.69 per cent. of vanillin, from Réunion vanilla 2.48 per cent., from Java vanilla 2.75 per cent. Stokeby found in vanilla, resin, wax, a fixed oil, a brown resinous matter, tannic acid changing the salts of iron to green, gum, sugar, phosphates and sulphates: hydrochloric acid separated from it oxalic acid, and potassium hydroxide, humic acid. (*J. P. C.*, 4e sér., iii, 76, 1866; see also paper by Clay W. Holmes, *Proc. A. Ph. A.*, 1887, 526.)

(See *Vanillinum*, PART I.)

Vanilla is used in the N. F. IV in making the *tincture of vanilla* (10 per cent. with a menstruum of alcohol and water), which is used as a flavoring agent in *elixir of ammonium valerate*, *elixir of hops*, *elixir of strychnine valerate* and *syrup of the bromides*.

Vanilla Poisoning.—Many years ago Orfila reported cases of violent gastro-intestinal irritation from eating vanilla ices, and since then others have reported similar instances of poisoning. In 1886 Vaughan in the investigation of an ice cream which had caused serious poisoning in eighteen persons found that the vanilla used to flavor it, in doses of 30 drops failed to produce any symptoms in either himself or his assistants, and he was able to separate the ptomaine tyrotoxicon, which he had previously found in other milk food (see *A. J. P.*, xvi, p. 452). It is highly probable that many of these cases are due to ptomaine poisoning rather than vanilla poisoning; but if the one reported by Rosenthal (*P. J.* xv, p. 24) be accurately stated it must be allowed that in some instances the vanilla itself is at fault. In this connection the reports of Claverie (*J. P. C.* Supp. 1908, xxv) of violent dermatitis in workmen handling vanilla beans is of interest. He attributes the symptoms to the oily exudate of the vanilla pods.

Vanillin Mercury. $(C_6H_3(OCH_3)(COH)O)_2Hg$.—This mercurial combination occurs as a white powder, tasteless and possessing a slight vanilla odor. It is insoluble in water, but soluble in dilute acids and has a mercury content of forty per cent. It is administered in the treatment of *syphilis*, both internally and hypodermatically.

Vasogen. *Vaselinum Oxygenatum.*—This is a feebly alkaline, yellow-brown fluid, of a peculiar but not disagreeable odor and taste, which readily emulsifies with water. It is said to be "oxygenated vaseline or petrolatum," and again that "it con-

tains about 25 per cent. of olein, saponified with anhydrous ammonia, and mixed with vaseline and vaseline oil." *Vasogen* serves as a vehicle for ointments whose active ingredients, it is said, are absorbed with great rapidity from the skin. There have been offered camphor vasogen, 33½ per cent.; iodine vasogen, from 3 to 10 per cent.; menthol vasogen, 2 per cent., and the list might be extended almost indefinitely.

There is a class of proprietary preparations of similar composition known as *petrogens* and there is also a group of preparations in the N. F. IV known as *petroxolins*, which are very similar.

Veratrole. *Pyrocatechin-di-methyl ester.* $C_6H_4(OCH_3)_2[1:2]$.—This is made by acting upon veratric acid with baryta in the presence of heat. It occurs as colorless crystals which melt at 23° C. (73.4° F.), and are soluble in alcohol, ether and the fixed oils. It is supposed to resemble guaiacol in its physiological action as it does in its composition. It is especially employed locally, mixed with equal parts of tincture of iodine in the treatment of intercostal *neuralgia*. It has also been administered internally in *tuberculosis* in *doses* of two grains (0.12 Gm.).

Verbascum. *Verbascum Thapsus* L. *Mullein. Flores Verbasci*, P. G. *Bouillon blanc, Molène*, Fr. *Wolkraut, Königskerze*, G. (Fam. *Scrophulariaceæ*.—The ordinary mullein weed is too well known to need description. As remedial agents both leaves and flowers have been employed. *Mullein Flowers* (*Verbasci Flores*) are official in the *N. F. IV* and are described as "the dried corollas, with adhering stamens, of *Verbascum phlomoides* Linné or of *Verbascum thapsiforme* Schraeder (Fam. *Scrophulariaceæ*). Preserve the flowers in tightly-closed containers. Corolla light-yellow, the outer surface grayish with a fine, soft, woolly indumentum, the inner surface sparsely hairy and finely veined; tube of the corolla only 1 or 2 mm. in length and almost equally broad, the limb from 14 to 30 mm. in breadth, between wheel-shaped and saucer-shaped, obscurely two-lipped, the unequal lobes rounded-obovate. Stamens five, borne on the base of the corolla, shorter than the corolla, two of them longer than the other three, the filaments thick and fleshy, more or less pilose, especially the three shorter ones, usually orange colored. Stamen-hairs cylindrical, unicellular, non-branching, surface minutely reticulate, apex rounded, frequently enlarged. Pollen grains smooth, triangular and more or less rounded, from 0.025 to 0.03 mm. in diameter. The flowers impart a yellow color to boiling water, and a rather permanent green color with dilute sulphuric acid, the latter color becoming brown upon the addition of alkalies. Odor peculiar, agreeable; taste mucilaginous, not agreeable. Mullein Flowers yield not more than 6 per cent. of ash." *N. F. Mullein Leaves* (*Verbasci Folia*) are official in the *N. F. IV* and are described as "the dried leaves of *Verbascum Thapsus* Linné (Fam. *Scrophulariaceæ*), and of other species of *Verbascum*. Obovate with narrowed base, or varying to oblong or oblong-lanceolate, without a true petiole, obtuse or tending toward acuteness at the summit, from 1 to 6 dm. in length and from 3 to 15 cm. in breadth; very thick, rather tough, light yellowish-gray or greenish-gray, densely long-tomentose, with numerous, multicellular, branching, non-glandular hairs. Nearly odorless; taste mucilaginous and slightly bitter. Verbascum yields not more than 14 per cent. of ash." *N. F.*

Mullein leaves are demulcent and emollient, and are thought to possess anodyne properties, which render them useful in pectoral complaints. On the continent of Europe, an infusion of the flowers, strained in order to separate the rough hairs, is considerably used in mild *catarrhs*. An oil, produced by saturating olive oil with mullein flowers, during prolonged exposure to the sun, is used as a local application in Germany for *piles* and other *mucous membrane inflammations*. The mullein oils sold in pharmacies are of this nature, or some of them alcoholic tinctures. The dried leaves are sometimes smoked to relieve irritation of the respiratory mucous membranes; fomentations with mullein leaves also have some repute as anodynes. Internally, the decoction (an ounce to the pint, flowering tips) may be taken in the quantity of from four to six fluidounces.

According to L. Rosenthal (*P. J.*, July, 1902), the seeds of *Verbascum sinuatum* L., which are used in Greece as a fish poison, contain 6.13 per cent. of saponin. Traces of the same substance were found in the fruits of *V. phlomoides* L. and *V. thapsiforme* Schrad.

Verbascum flowers were introduced in the N. F. IV as one of the ingredients in *Pectoral species*, and the leaves in *Fluidextract of mullein leaves* made with diluted alcohol.

Dose, one to two drachms (3.9–7.8 Gm.).

Verbena. *N. F. IV. Blue Vervain.*—"The dried overground portion of *Verbena hastata* Linné (Fam. *Verbenaceæ*), collected when flowering." The plant is a tall shrub growing in damp situations throughout the United States. "In broken or cut pieces; stem stout, obtusely quadrangular, rough, pubescent; leaves opposite, petioles from 12 to 25 mm. in length, blades from 6 to 12 cm. in length, lanceolate, acuminate, acute, coarsely and sharply serrate or the lower hastate lobed, deep green above, paler beneath, conspicuously veined; flowers in terminal interrupted panicles of spikes, spikes erect cylindraceous, densely flowered, each flower subtended by a lanceolate acute bract; calyx adherent, little more than half the length of the corolla, tubular, five-lobed, the mouth slightly oblique; corolla small, bright blue, salver-form tube externally pubescent, sub-equally five-lobed; stamens adnate to the corolla tube, included, didynamous; fruit dividing at maturity into four one-seeded parts. Odor heavy, especially if dampened; taste bitter and disagreeable. Verbena yields not more than 10 per cent. of ash." *N. F.* The *fluidextract of verbena* is official in the N. F. (See Part III.) There is no reason to suspect it of medicinal virtue. The *dose* stated in the N. F. is fifteen grains (1 Gm.).

Verditer.—Two preparations of copper, employed as pigments, are known by this name in commerce, and are distinguished by the epithets of blue and green. *Blue verditer* is prepared in London from the solution of copper nitrate obtained in precipitating silver by copper. According to Gray, this solution is poured while hot upon whiting calcium carbonate, and the mixture stirred every day till the liquor loses its color, when it is decanted, and fresh portions added till the proper color is obtained. By a process for procuring this pigment, invented by Pelletier, the solution of copper nitrate is decomposed by quicklime, and the precipitate, after being washed, is incorporated intimately with another portion of quicklime. By the former process, a copper carbonate is obtained; by the latter, a mixture of copper and calcium hydroxides. *Green verditer*

is prepared by precipitating a solution of copper nitrate by chalk or a white marl, and consists of copper carbonate mixed with an excess of the calcareous carbonate.

Veronal Sodium. *Sodium dimethylbarbiturate.* $Na(C_8H_{11}O_3N_2)$. *Sodium Veronal. Medinal.*—This preparation has the advantage over veronal that it is much more soluble in water, it requiring only six times its weight to dissolve it, according to Puckner and Hilfert. (*J. A. M. A.*, Jan. 23, 1909.)

Because of its freer solubility, medinal acts more promptly than veronal. It may be used for the same purposes as veronal in *doses* of five to fifteen grains (0.3–1 Gm.). Munk (*Med. Klin.*, iv, p. 1834) has also employed it hypodermically in the form of a ten per cent. solution. The injections are somewhat painful, because of the large volume of the injection.

Vernonia. *Vernonia anthelmintica* Willd. (Fam. *Compositæ.*)—This is an East Indian plant, whose black, bitter, and nauseous seeds have a high reputation in Ceylon as an anthelmintic in *doses* of sixty grains (3.9 Gm.). (*P. J.*, April, 1883; also *Ph. Rev.*, 1896, 274.)

Veronica. *Veronica officinalis* L. *Speedwell. Véronique mâle*, Fr. *Ehrenpreis*, G. (Fam. *Scrophulariaceæ.*)—Several species of *veronica*, common to Europe and this country, have been medicinally employed. Of these, *V. officinalis* L., and *V. Beccabunga* L., or European *brooklime*, are the most conspicuous. *V. officinalis* has a bitterish, warm, and somewhat astringent taste. Enz found in it a bitter principle soluble in water and alcohol, but scarcely so in ether, and precipitated by the salts of lead, but not by tannic acid; an acrid principle; red coloring matter; a variety of tannic acid producing a green color with ferric salts, a crystallizable fatty acid, with malic, tartaric, citric, acetic, and lactic acids; mannite; a soft, dark green, bitter resin. Mayer, of New York, found evidences of an alkaloid and of a saponaceous principle. (*A. J. P.*, 1863, 209.) Vintilesco found a glucoside in *V. officinalis* and *V. chamædris*. (*J. P. C.*, 1910, No. 4.) The plant has been considered diaphoretic, diuretic, expectorant, tonic, etc., and was formerly employed in *pectoral* and *nephritic complaints, hemorrhages, diseases of the skin*, and in the treatment of *wounds*. *V. Beccabunga* was used in the fresh state in *scurvy*.

Viburnum Opulus. *N. F. IV (U. S. P. VIII). High Bush Cranberry Bark. Cramp-bark. Wild Guelderrose. Cherry-wood. Red or Rose Elder. Pincushion Tree. Squaw Bush; in cultivation Snowball Bush. Obier*, Fr. *Wasserholderrinde. Wasserschwelke*, G.—"The dried bark of *Viburnum Opulus* Linné var *americanum* (Miller) Aiton (Fam. *Caprifoliaceæ*), without the presence of more than 5 per cent. of wood and other foreign matter." *N. F.*

Viburnum Opulus, cranberry tree or *high bush cranberry*, belongs to the section of the genus which has peduncled cmyes, light red, acid, roundish drupes, with very flat orbicular not sulcate stones, palmately veined leaves, and scaly winter buds. It is a large bush, reaching the height of ten feet, growing in low grounds from New Brunswick far westward, and southward to Pennsylvania. The leaves are from three- to five-ribbed, strongly three-lobed, broadly wedge-shaped or truncate at the base, with the spreading pointed lobes mostly toothed in the sides and entire in the sinuses. The petioles bear two glands at the apex. The *snow-ball tree*, or *Guelder rose*, is a variety in which the whole inflorescence has been turned into a mass of showy sterile flowers.

"In strips, or occasionally in quills or chip-like fragments, the bark attaining a thickness of 3 mm.; outer surface of the thinner pieces of a light gray color with crooked, longitudinal, purplish-brown stripes and very small brown lenticels, the thicker pieces purplish-red or occasionally blackish, except when very young, and more or less finely fissured or thinly scaly; inner surface varying in color from yellowish to rusty-brown, with very short oblique striæ, except where the outer wood layer adheres; fracture short and weak, the fractured surface mostly whitish, varying to pale brown in the inner layer, rusty brown in the outer layer, covering the green tangential layers of phelloderm. Odor strong and characteristic; taste mildly astringent and decidedly bitter. Under the microscope, sections of Viburnum Opulus show as outer corky layer, of five to twenty-five rows of cells, the walls being nearly colorless, frequently thickened on the inner surface, individual cork cells from 0.015 to 0.045 mm. in radial diameter and from 0.030 to 0.075 mm. in tangential diameter; outer bark of about ten rows of cells containing a brownish-yellow, amorphous substance, small starch grains or chloroplastids; medullary rays one to two cells in width, usually not more than one-cell wide; inner bark with occasional groups of bast fibers composed of one to ten cells, the walls being very thick, non-lignified, lamellated and finely porous; adhering wood with large tracheæ having scalariform or reticulate thickenings, and being surrounded by wood fibers with thick lignified walls; starch grains, mostly in cells of parenchyma and medullary rays, either single or compound, the individual grains not exceeding 0.006 mm. in diameter; calcium oxalate in rosette aggregates, 0.015 to 0.04 mm. in diameter, numerous fragments of parenchyma cells, the lumina filled with a reddish-brown amorphous substance. The powder of Viburnum Opulus is light grayish-brown, consisting of irregular fragments; polygonal cork cells, with thin, colorless walls; parenchyma with rosette aggregates of calcium oxalate, from 0.015 to 0.04 mm. in diameter; starch grains very small and mostly in parenchyma cells; fragments of parenchyma containing a brownish-yellow amorphous substance; occasional tracheal fragments associated with lignified wood fibers, bast fibers and stone-cells." *N. F.*

For studies of Viburnum barks, see *A. J. P.*, 1895, 378, 394; also *Ph. Post.* 35, 773, Gibson (*Proc. Indiana Pharm. Assoc.*, 1900, 112) believes that there is a glucoside present in the bark of *V. Opulus;* he describes it as resinous, greenish in color, soluble in alcohol, slightly soluble in water.

The berries of this plant are used to a considerable extent as a substitute for the ordinary cranberry, and are antiscorbutic, but there is no sufficient reason to believe the bark has any medicinal properties of any kind. *V. obovatum* Walt., a tree shrub growing from Virginia southward, is said to be an antiperiodic. (*A. J. P.*, 1878.) Viburnum opulus was dismissed from the U. S. P. IX, but introduced in the N. F. IV. It is used in making *Fluidextract of Viburnum Opulus* with a menstruum of 2 volumes of alcohol and 1 volume of water. *Compound Tincture of Viburnum*, and *Compound Elixir of Viburnum Opulus*. *Dose*, thirty to sixty grains (2.0–3.9 Gm.).

Vieirine.—This substance is obtained from the bark of the *Remijia Velloxii*, DC. (Fam. *Rubiaceæ*), of Brazil. It is used in Brazil in *doses* of from one to four grains (0.065–0.26 Gm.) repeated *pro re nata*, as a tonic and as an antiperiodic in place of quinine.

Vienna Paste. *Potassa Cum Calce. U. S.* 1890. *N. F. IV. Potassa with Lime.*—This is official in the N. F. IV (see Part III). It is "a grayish-white powder, deliquescent, having a strongly alkaline reaction, and responding to the tests for calcium and potassium. It should be soluble in diluted hydrochloric acid without leaving more than a small residue." *U. S.*, 1890. It should not effervesce on the addition of an acid. It is prepared for use by being made up into a paste with a little alcohol. The paste is applied for ten or fifteen minutes to the part to be cauterized, exactly as with potassium hydroxide, than which escharotic it is more manageable, being slower in its operation, and less deliquescent. Filhos has improved this caustic by forming it into sticks. To prepare it thus, the potassium hydroxide is perfectly fused in an iron spoon, and one-third of its weight of quicklime is added in divided portions, the whole being stirred with an iron rod. The fused mass is then run into lead tubes, closed at one end, about three inches long, and from a quarter to half an inch in diameter in the clear. The sticks are kept, still enclosed in the lead tubes, with the open end downward, in thick glass tubes, containing some powdered quicklime, and closed with a cork, between which and the stick some cotton is put to steady the caustic. When employed, as much of the caustic is uncovered at the end by scraping off the lead, as it is proposed to use.

Viferral. *Polychloral.*—A polymerization product of chloral and pyridin. It forms a white powder of disagreeable taste and fuses at 153° to 155° C. (307.4°–311° F.). Alkalies react on it, splitting it up into chloroform and formic acid. When heated with dry potassium hydroxide it develops the unpleasant isonitril odor. It is slightly soluble in cold and readily so in hot water. It is used as a hypnotic, asserted to be superior to chloral, due to its non-toxicity. *Dose*, twelve to fifteen grains (0.8–1.0 Gm.).

Vinca.—Under this name are included *V. major* L., *Greater Periwinkle*, and *V. minor* L., *Lesser Periwinkle* (Fam. *Apocynaceæ*). It is said to be very useful in arresting *menorrhagic* and other *hemorrhages*. (*P. J.*, 1871, 961; *Ibid.*, 1873, 963; also *A. J. P.*, 1872.)

Vincetoxicum. *V. officinale* Moench. (now more properly *Cynanchum Vincetoxicum* (L.) Pers. *White Swallow-wort. Vincetoxicum. Asclépiade, Dompte-venin, Hirundinaire*, Fr. *Schwalbenwurz, Giftwende*, G.—A perennial, herbaceous European plant, the root of which was formerly esteemed a counterpoison, and hence the botanical name. It has a bitterish, acrid, taste, and, when fresh, a disagreeable odor, which is diminished by drying. Kubler found a glucoside, *vincetoxin*, $C_{50}H_{82}O_{20}$, which he states differs from *condurangin* which other investigators asserted to be identical. (*A. Pharm.*, 1908, 659.) Taken internally, especially in the recent state, it excites vomiting, and is capable, in larger quantities, of producing dangerous, if not fatal, inflammation of the stomach. Feneulle found in the root a principle analogous to emetin. It has been used in *skin diseases* and *scrofula*.

Vinegar. *Acetum.*—*Vinegar* is produced by the acetous fermentation in infusion of mixed malted and unmalted grain, or of various fruit juices. Any substance which is capable of undergoing the alcohol fermentation is further liable, under the influence of a microscopic plant, *Mycoderma aceti*, first described by Pasteur, and exposure to the air at a temperature between 24° C. (75° F.) and 35° C. (95° F.), to undergo further change with oxidation, which converts the alcohol into acetic acid. Practically for success there should not be more than 12 per cent. of alcohol in the original fluid. The mycoderm may exist as a pellicle composed of extremely small cells (micrococci) in contiguous rows, or finally enveloped in a glue-like mass, or it may be in the form of rod-like cells (bacilli) more or less dispersed through the fluid. There are a number of other organisms which oxidize alcohol into acetic acid, viz., *Bacterium aceti*, *B. Pasteurianum*, *B. Kuetzingianum*, *B. Oxydans*, and *B. Industrium*.

In the quick *German process* for making vinegar a mixture of one part of 80 per cent. alcohol, four or six parts of water, and one-thousandth of honey or extract of malt, at a temperature of 24° C. (75° F.) to 35° C. (95° F.), is allowed to percolate through beech shavings, previously steeped in vinegar, and contained in a deep oaken tub, in which is a wooden diaphragm perforated with numerous small holes, loosely filled with packthread about six inches long. It is essential to the success of the process that a current of air shall pass through the tub. In order to establish this current, eight equidistant holes are pierced near the bottom of the tub, forming a horizontal row, and four glass tubes are inserted vertically in the diaphragm, of sufficient length to project above and below it. The air enters by the holes below, and passes out by the tubes. Although the air is necessary for the furnishing of oxygen, acetification consisting chiefly in the oxidation of the alcohol, the beech shaving and similar articles chiefly aid in the process by affording surface upon which the mycoderms can grow. During the process the temperature rises to 37° C. (100° F.) or 40° C. (104° F.), and remains nearly stationary while the process is going on favorably. The liquid is drawn off by a discharge pipe near the bottom, and must be passed three or four times through the tub before the acetification is completed, which generally occupies from twenty-four to thirty-six hours. According to Wimmer, pieces of purified charcoal, about the size of a walnut, may be advantageously substituted for the beech shavings in the process.

In 1862, Pasteur substituted for the German process the sowing of the mycoderm upon the surface of a mixture of wine and vinegar, or of water, alcohol (2 per cent.), and acetic acid (1 per cent.) adding alcohol daily in small quantities after about half that contained in the original liquid had been converted into acetic acid, until a vinegar of sufficient strength was produced. The *French process* was improved in 1869 by Laugier, and it was subsequently further elaborated by Emanuel Wurm. (For details, see *P. J.*, xi, 133.)

In England, vinegar is made from the infusion of malt. The fermented wort is caused to fall in a shower upon a mass of fagots of birch twigs occupying the upper part of a large vat, and, after trickling down to the bottom, is pumped up repeatedly to the top, to be again allowed to fall, until the acetification is completed. This mode of

oxidizing the alcohol in the fermented wort has the advantage of rendering insoluble certain glutinous and albuminous principles, which, if not removed, would cause a muddiness in the vinegar and make it liable to spoil.

In the United States, vinegar is largely made by the German method of oxidizing very diluted alcohol, and is called *spirit vinegar;* it is often prepared from cider—*cider vinegar.* The cider is placed in barrels (with their bung holes open) which are exposed during the summer to the heat of the sun. The acetification is completed in the course of about two years. The progress of the fermentation, however, must be watched, and as soon as perfect vinegar is formed, it should be racked off into clean barrels. Without this precaution, the acetous fermentation would run into the putrefactive, and the vinegar spoiled. Cider vinegar contains no aldehyde. It contains malic acid, and therefore yields a precipitate with lead acetate. The want of such a precipitate indicates that the alleged cider vinegar is a manufactured substitute, although a fictitious article might yield a similar precipitate.

Vinegar may be clarified, without impairing its aroma, by throwing about a tumberful of boiling milk into from fifty to sixty gallons of the liquid, and stirring the mixture. This operation also makes red vinegar pale.

The series of changes which occur during the *acetous fermentation* is called *acetification.* During its progress there is a disengagement of heat; the liquor absorbs oxygen and becomes turbid; filaments form, and upon the completion of the fermentation, form a pultaceous mass, leaving a clear liquor containing the acetic acid. The explanation of Liebig is that the alcohol loses two atoms of hydrogen as the first effect of oxidation, and becomes aldehyde, and this, by the absorption of one atom of oxygen, becomes acetic acid ($C_2H_3O.OH$). Thus the conversion of alcohol into acetic acid consists in, first, the removal of two atoms of hydrogen, and afterwards the addition of one atom of oxygen. The following equations represent this change:

$$C_2H_6O + O = C_2H_4O + H_2O$$
$$C_2H_4O + O = C_2H_4O_2$$

Aldehyde is a colorless, inflammable, ethereal liquid, having a pungent taste and odor. Its specific gravity is 0.79. It absorbs oxygen gradually, and is thus converted into acetic acid, as just stated. Its property of absorbing oxygen gives it a reducing power like that possessed by glucose. Hence it responds to Fehling's test for that substance (PART III). It is characterized by its forming a crystalline compound with ammonia, and also with alkaline bisulphites; it is polymerized by the action of acids and some other reagents, and thus yields *paraldehyde* $(C_2H_4O)_3$, a liquid boiling at 124° C. (255° F.). The name aldehyde alludes to its relation to alcohol, *alcohol dehydrogenated.* Its aqueous solution is decomposed by potassium hydroxide with formation of *aldehyde resin.* This is a soft, light brown mass, which, heated to 100° C. (212° F.), gives off a nauseous soapy odor.

Properties.—Vinegar, when good is of an agreeable, penetrating odor, and a pleasant acid taste. According to Magnes-Lahens, wine vinegar always contains a little aldehyde. The better sorts of vinegar have a grateful aroma, probably due to the presence of an ethereal substance, perhaps acetic ether. The color of vinegar varies from pale yellow to deep red. When long kept, especially if exposed to the air, it becomes ropy, acquires an unpleasant odor, putrefies, and loses its acidity.

The essential ingredients of vinegar are acetic acid and water; but, besides these, it contains various other substances, derived from the particular vinous liquor from which it may have been prepared. Among these may be mentioned coloring matter, gum, starch, gluten, sugar, a little alcohol, and frequently malic and tartaric acids, with a minute proportion of alkaline and earthy salts. Vinegar should be devoid of lead and copper and of free sulphuric acid, as shown by its not being discolored by hydrogen sulphide, and yielding no precipitate when boiled with a solution of calcium chloride, and of such a strength that a fluidounce would require, for neutralization, not less than thirty-five grains of potassium bicarbonate. After neutralization it should be free from acrid taste, indicating the absence of acrid substances, the taste of which may have been concealed by that of the acetic acid.

Malt Vinegar (*Acetum Britannicum*) has a brown color, and a sp. gr. from 1.006 to 1.019. The strongest kind, called *proof vinegar,* contains from 4.6 to 5 per cent. of acetic acid. That of British manufacture usually contains sulphuric acid, which the manufacturer is allowed by law to add in a proportion not exceeding one part in a thousand; but if the vinegar be properly made it does not require to be thus protected.

Malt Vinegar is "a liquid of a brown color and peculiar odor. Specific gravity 1.017 to 1.019. 445.4 grains by weight (1 fluidounce) of it require about 402 grain-measures of the volumetric solution of soda for their neutralization, corresponding to 5.41 per cent. of real acetic acid, $HC_2H_3O_2$. If ten minims of solution of barium chloride be added to a fluidounce of the vinegar, and the precipitate, if any, be separated by filtration, a further addition of the test should give no precipitate. Sulphuretted hydrogen causes no change of color." *Br.,* 1885.

Wine Vinegar (*Acetum Gallicum*) is nearly one-sixth stronger than pure malt vinegar. It is of two sorts, the white and the red, according as it has been prepared from white or from red wine. *White wine vinegar* is usually preferred. *Red wine vinegar* may be deprived of its color, and rendered limpid, by being passed through animal charcoal. Under the name of wine vinegar or white wine vinegar the so-called distilled vinegar is sometimes sold. This is made, not by distillation of vinegar as the name indicates, but by the distillation of a weak alcoholic liquid produced by the fermentation of molasses with yeast and the subsequent acetification of the weak alcohol by percolation through beechwood shavings impregnated with mycoderma aceti.

The best test for the detection of free inorganic acids is a weak solution of methyl violet which turns green in the presence of free inorganic acids, but remains unaffected by organic acids.

Distilled Vinegar (*Acetum Destillatum; Vinaigre distillé, Oxéolat simple,* Fr.; *Destillirter Essig,* G.) was official in the U. S. Pharmacopœia, 1870, and was prepared by obtaining seven pints of distillate from eight pints of vinegar placed in a glass retort, the one pint left in the retort retaining the fixed impurities, salts, etc. One hundred grains should saturate not less than seven and six-tenths grains of potassium bicarbonate.

Adulterations.—The principal foreign substances which vinegar is liable to contain are sulphuric and sulphurous acids, and copper and lead, derived from improper vessels used in its manufacture. Tin has been found in it after standing a short time in tin vessels.

Barium chloride is not a suitable test for the presence of free sulphuric acid, as it will cause a precipitate with sulphates, which are often found in vinegar when no free sulphuric acid is present.

By far the most dangerous impurities in vinegar are copper and lead. The former may be detected by a brownish precipitate on the addition of potassium ferrocyanide to the concentrated vinegar; the latter, by a blackish precipitate with hydrogen sulphide, and a yellow one with potassium iodide. Pure vinegar is not discolored by hydrogen sulphide. According to Chevallier, wine vinegar which has been strengthened with acetic acid from wood sometimes contains a minute proportion of arsenic, which is probably derived from arseniferous sulphuric acid, employed in preparing the acetic acid. (For an examination of samples of commercial vinegar by F. G. Ryan, see *A. J. P.*, 1899, p. 71; see also Leach's *Food Analysis*, 3rd edition.)

Vinegar has feeble antiscorbutic properties, but is at present used as a medicine only for its local astringent properties, and in the form of an enema diluted with three times its bulk of water to kill *seat worms*. In the *dermatitis* produced by exposure to the sun, made into a paste with glycerin, bismuth, and starch, it is very effective. In *hematemesis* one ounce to a tumbler of water often acts very advantageously, and may be taken freely. At one time vinegar was largely used in pharmacy as a menstruum, but on account of its tendency to undergo decomposition it has been replaced by diluted acetic acid in both the American and British Pharmacopœias.

Vinegar of Ipecacuanha. *Br.* 1898. *Acetum Ipecacuanhæ.*—"Liquid Extract of Ipecacuanha, 1 fluidounce (Imperial measure) or 50 mils; alcohol (90 per cent.), 2 fluidounces (Imperial measure) or 100 mils; Diluted Acetic Acid, 17 fluidounces (Imperial measure) or 850 mils. Mix; filter, and, if necessary, add sufficient diluted acetic acid to produce one pint (Imperial measure) or one thousand mils of the Vinegar of Ipecacuanha." *Br.*, 1898. Diluted Acetic Acid is a good menstruum for ipecacuanha, and this vinegar will doubtless prove effective as an expectorant. (For uses see *Ipecacuanha.*) *Dose*, five to forty minims (0.3 to 2.5 mils).

Vioform. *Nioform.* $C_9H_5NOHICl$. *N. N. R.* 1917.—*Iodo-chloroxyquinoline* was introduced as a substitute for iodoform in surgery. It is a greenish-yellow, almost odorless, bulky, insoluble powder. According to the researches of E. Tavel, it is less toxic than iodoform, especially when brought in local contact with wounds, and is also more actively germicidal than is iodoform. Locally it is not at all irritant. (See *S. Jb.*, Bd. 267, p. 133; Bd. 272, p. 163.)

Viola. *Violet.*—The genus *Viola* (Fam. *Violaceæ*) includes numerous species, many, perhaps all of which are possessed of analogous medicinal properties. *Viola tricolor* L., the *Heart's-ease, Pansy,* or *Johnny-jump-up* of the gardens, was formerly recognized by the U. S. Pharmacopœia; while *V. odorata* L., and *V. pedata* L., have held places in both the British and the United States Pharmacopœias.

V. odorata L. (*Violette, Violette odorante,* Fr.; *Wohlriechendes Veilchen, Veilchen,* G.; *Violetta,* It.; *Violeta,* Sp.), the common violet of Europe, resembles very closely the American blue violet, *V. cucullata* Ait., from which, however, it is at once distinguished by its delicious fragrance. It is the *sweet violet* of our gardens. *V. pedata* L., is an indigenous, stemless violet, characterized by its large blue or variegated beardless flowers, and its deeply three- to five-divided, pointed pedate leaves.

The flowers of *V. odorata* yield their odor and their slightly bitter taste to boiling water. Their infusion affords a delicate test for acids and alkalies, being reddened by the former and rendered green by the latter. Their odor is destroyed by desiccation, and the degree to which they retain their fine color depends upon the care used in collecting and drying them. They should be gathered before being fully blown, deprived of their calyx, and rapidly dried, either in a heated room or by exposing them to a current of very dry air. The flowers of other species are often mingled with them, and, if of the same color, are equally useful as a chemical test.

In the root, leaves, flowers, and seeds of *Viola odorata,* Boullay discovered an alkaloid, *violine,* allied to emetine, but possessing distinct properties. It exists in the plant combined with malic acid. Orfila asserts that it is exceedingly active and even poisonous. It is probably found in other species of *viola.* Mandelin (*Jahresb.*, 1883) obtained a glucoside analogous to quercitrin, which he names *viola-quercitrin.* It crystallizes out of hot water in fine yellow needles. When boiled with diluted acids, it is decomposed into *quercetin, isodulcite* and a fermentable glucose,

$$C_{27}H_{30}O_{16} + 3H_2O = C_6H_{14}O_6 + C_6H_{12}O_6 + C_{15}H_{10}O_7$$

he also obtained salicylic acid from several species of viola. (*A. J. P.*, 1882, 10.) Kraemer (*Inaug. Diss.*, Marking, 1896) detected methyl salicylate and this was later confirmed by Schimmel & Co. See also Gadd's article, *Y. B. P.*, 1905, 466.

The herbaceous parts of various species of violets are mucilaginous, emollient, and slightly laxative, and have been used in *pectoral, nephritic,* and *cutaneous diseases.* In Europe a syrup prepared from the fresh flowers of *Viola odorata* is employed as an addition to demulcent drinks, and as a laxative for infants. The root, which has a bitter, nauseous, slightly acrid taste, acts in the *dose* of from thirty grains to a drachm (2.0–3.9 Gm.) as an emetic and cathartic. It is probable that the same property is possessed by the roots of all the violets, as it is known to be by several species of *Ionidium,* which belongs to the same family. The existence in small proportion of the emetic principle in the leaves and flowers accounts for their expectorant properties.

Virginia Creeper. *Psedera quinquefolia* (L.) Greene (*Parthenocissus quinquefolia* (L.) Planch. *Ampelopsis quinquefolia* Michx.) *American Ivy. Vigne vierge,* Fr. *Wilder Wein, Amerikanischer Epheu,* G.—The bark twigs of this indigenous, woody creeper of the fam. *Vitaceæ* have been used by the eclectics as an alterative, tonic, and expectorant. They contain tartaric acid and potassium and calcium tartrates, albumen, sugar, pyrocatechin, and some other principles. McCall employed the bark collected late in the fall in *dropsy,* with asserted very good results. (*Penins. and Independ. Med. Journ.*, June, 1858.) In two cases

of poisoning reported by Bernays, the symptoms were violent vomiting and purging, collapse, and deep sleep, with dilated pupils. (*P. J.*, vii.)

Viscum. *Viscum album* L. *Mistletoe. Gui de Chêne, Gillon,* Fr. *Mistel,* G. (Fam. *Loranthaceæ.*)—A European evergreen, parasitic shrub growing on various trees, particularly the apple and other fruit trees, and forming a pendent bush from two to five feet in diameter. The plant is famous in the history of Druidical superstition. In the religious rites of the Druids, the mistletoe of the oak was employed, and hence was afterwards preferred when the plant came to be used as a remedy; but it is in fact identical in all respects with those which grow upon other trees. (*P. J.*, 1897, 289.) The fresh bark and leaves have a peculiar, disagreeable odor, and a nauseous, sweetish, slightly acrid and bitterish taste. *Viscin,* which forms the glutinous constituent in the berries, leaves, and stalks of the mistletoe, is the principal constituent of *birdlime.* Crude viscin may be obtained by kneading the finely bruised mistletoe bark with water, as long as anything is dissolved, and removing the ligneous impurities mechanically. A purer product may be obtained by boiling the crude product in strong alcohol, macerating the residue with ether, evaporating the ethereal extracts, purifying these extracts by kneading first with alcohol and then with water. The formula $C_{20}H_{48}O_8(C_{20}H_{32} + 8H_2O)$ has been given to it by Reinsch. Pawlevsky (*Bull. Soc. Chim.* (2), 34, 348) obtained from mistletoe a crystallizable acid, slightly soluble in water, insoluble in alcohol and ether, fusing at from 101° to 103° C. (213.8°–217.4° F.), to which he gave the formula $CH_3O_3.OH$. The berries, which are white, and about the size of a pea, abound in the peculiar viscid principle, and are sometimes used in the preparation of birdlime, of which this principle is the basis. Mistletoe is said to be productive of vomiting and purging when largely taken. The berries caused in a child three years old vomiting and prostration, coma, a fixed and somewhat contracted pupil, and convulsive movements. (*Ann. Thér.*, 1859, 36.) A fatal case is recorded. (*M. T. G.*, 1867, 26.) The plant was formerly looked upon as a powerful nervine, but it is now out of use. The leaves and wood were given in the *dose* of a drachm (3.9 Gm.) in substance. *Viscum* has been recommended by Gaultier (*S. M.*, 1907) for the reduction of high blood pressure in *arterio-sclerosis* and other conditions of excessive arterial tension. But Dossin (*A. I. P. T.*, 1911, xxi, p. 432) finds that the lowering of blood pressure is of but short duration and is preceded by a rise and concludes, therefore, that the drug is not clinically useful for this purpose. Gaultier employed a watery extract in *doses* of 3 grains (0.2 Gm.) daily. According to P. Riehl (*D. M. W.*, xxvi, 1900), viscin affords an excellent basis for the making of applications to the skin, a benzene viscin solution mixed with starch affording an excellent plaster mass.

The *American Mistletoe* is the *Phoradendron flavescens* (Pursh) Nutt. It is a woody parasite, growing upon the branches of deciduous trees from New Jersey to Florida and westward. It is probably the plant reported as growing upon the elm, by which several children were poisoned. (Henry Dye, *Memphis Med. Recorder,* iv, 344.) The prominent symptoms were vomiting and great thirst followed by frequent discharge of bloody mucus from the bowels, with tenesmus. One of the children was found in a collapsed state, in which death took place. Dye states also that, in other instances, as he had been informed, children had eaten the *berries* without any ill effect. In the western part of the United States *Arcenthobium Americanum* Nutt., and *Phoradendron juniperinum* Englm., are also known under the name of mistletoe. Crawford (*J. A. M. A.*, 1911, lvii) has found that the extract of *P. flavescens* or the *P. juniperinum,* when injected into the blood stream, produces a sharp rise in the blood pressure similar to that produced by epinephrine. He also succeeded in isolating an active base, the composition of which, however, he did not satisfactorily determine, but suggests that it may be phenylethylamine. W. H. Long, confirmed by Lee Payne (*North Carolina Med. Journ.*, vol. vii, 253) asserts (*New Prep.*, ii, 31) that the American mistletoe is a very certain oxytocic, and very efficacious in arresting post-partum and other varieties of *uterine hemorrhage.* He gives a fluidrachm (3.75 mils) of the fluidextract every twenty minutes in labor until the effect is produced; every four to six hours in *menorrhagia.* Dalassus proposes a formula for an aqueous *extract of mistletoe.* Five hundred parts of the ground, dry, young twigs and leaves are infused for 12 hours in 3000 parts of boiling water, expressed and the residue treated with 1500 parts of boiling water. The united liquids are then evaporated to the consistence of an extract. *Syrup of mistletoe* is made by dissolving 1 part by weight of the above extract in 10 parts by weight of boiling water and adding 990 parts of simple syrup.

Vitex.—The various species of this genus have been attributed by the ancients with wonderful powers, and the *V. trifolia* is still used occasionally for medicating baths.

Warburg's Tincture.—This famous remedy, at first a proprietary medicine, afterwards by the voluntary act of its inventor had its formula revealed. It is now official in the N. F. IV (see Part III). There is so much testimony as to its extraordinary virtues in the severe *remittent* and *pernicious malarial fevers* of India that its powers can scarcely be questioned. After the bowels of the patient in the acutest stage of the disorder have been freely opened, a half ounce of the tincture is given undiluted, all drink being withheld, and at the end of three hours a second half ounce is given in a similar manner. Soon after the second dose a violent, aromatic perspiration comes on, and the fever is usually broken. The remedy is also commended in *collapse* without organic disease. The formula given by Warburg is as follows: Socotrine aloes 1 lb.; rhubarb, angelica fruit, confection of Damocratis, each 4 oz. troy; elecampane, saffron, fennel, prepared chalk, each 2 oz. troy; gentian, zedoary, cubebs, myrrh, camphor, agaric, each, 1 oz. troy. Digest the whole with 500 oz. proof spirit in a water bath for 12 hours express, add 10 oz. sulphate of quinia, dissolve by the aid of a water bath, cool, and filter.

It is evident that *Warburg's tincture* contains various substances which are inert, but the practical difficulty is to determine as to what its extraordinary value anti-malarial powers are really due. The formula of Hager—quinine sulphate 1 part, spirit of camphor 2 parts, elixir proprietatis (P. G.), 22 parts, alcohol, 16 parts—does not seem to us to at all represent the tincture. The formula used in the U. S. army, with asserted excellent results in Cuba, has the advantage of yielding a product in tablets, which is as follows: Aqueous extract aloes, 224 grains; rhubarb, 448 grains; angelica seed, 448 grains; elecampane, 224 grains; saffron (Spanish), 224 grains; fennel, 224 grains;

gentian, 112 grains; zedoary root, 112 grains; cubeb, 112 grains; myrrh, 112 grains; white agaric, 112 grains; camphor, 112 grains; quinine sulphate, 1280 grains. Exhaust with eight pints of diluted alcohol, or divide into 1024 tablets.

The confection of Damocratis, in the original, which was a combination of thirty aromatic substances mostly obsolete, may be found in the 19th ed., *U. S. D.*, p. 1695. It is contained in the formula in such small amount that it is hardly possible that it could have any effect. (See also *Tinctura Antiperiodica*, N. F., Part III.)

The National Formulary has revised the formula of Warburg's tincture and there are two tinctures, one with and one without aloes.

Dose.—The dosage of Warburg's tincture depends on the kind used—whether with aloes or without—and the intended purpose, and varies from 4 mils (1 fluidrachm) to 15 mils (4 fluidrachms). The larger quantity is given when Dr. Warburg's original directions are followed for administering the remedy in remittent fevers. These directions were as follows: "One-half ounce to be given alone, without dilution, after the bowels have been evacuated by any convenient purgative, all liquids being withheld. After three hours another half ounce is to be given."

White Ash Bark. *N. F. IV. Fraxinus.*—It is described as "the dried bark of *Fraxinus americana* Linné (Fam. *Oleaceæ*) and probably of other species of *Fraxinus*, deprived of the corky layer. In flat pieces of varying length and width, from 3 to 6 mm. in thickness, externally yellowish or pale brown, sometimes with ridges of a warty nature and fissures of a grayish-brown color with markings of lichens; inner surface, pale brown to yellowish, longitudinally striate; fracture very uneven, fibrous. Odor faintly aromatic; taste bitter, weakly acrid. Fraxinus yields not more than 10 per cent. of ash." *N. F.* A large forest tree of the northern United States and Canada. It contains a volatile oil, an alkaloid and several resins. The bark has been used in *dysmenorrhea* by Charles P. Turner and others. A *wine* is official in the N. F. (see Part III).

Fraxinus excelsior L. *Frêne*, Fr. *Esche*, G. *Fresco*, Sp. (Fam. *Oleaceæ.*)—The bark of the *Common European Ash* occurs in quills and is of a grayish or grayish-green color. It is bitter and astringent, and at one time was employed in the treatment of *intermittent fever.* It contains a crystalline glucoside and a bitter principle, and a fixed oil obtained from the seeds. (*Chem. Ztg.*, 1911, 478.) The leaves have long been used in *rheumatic affections* and *gout.* Garot has shown that they contain 16 per cent. of *calcium malate.* (See *J. P. C.*, 3e sér., xxiv, 311; also 4e sér., xii, 60.) *Dose*, an ounce (31 Gm.), infused in half a pint (236 mils) of boiling water, three times a day. (See *Am. J. M. S.*, N. S., xxv, 492.)

White Pine Bark. *N. F. IV. Pinus Alba.*—"The dried inner bark of *Pinus Strobus* Linné (Fam. *Pinaceæ*)." *N. F.* "In flat pieces of variable size and from 1 to 3 mm. in thickness; outer surface varying from a pale pinkish-white when fresh, to a light or rather deep yellowish-brown on keeping, occasionally with small patches of the gray-brown periderm adhering; more or less cottony, and often showing small scattered pits; inner surface either lighter or darker than the outer, finely striate; fracture tough, fibrous; transverse section showing an outer yellowish and an inner whitish band. Odor slight, terebinthinate; taste slightly mucilaginous, bitter, sweet and astringent. The powdered drug, when examined under the microscope, exhibits numerous rounded or oval, simple starch grains, up to 0.03 mm. in diameter, some having a cleft or fissure through the center; few monoclinic prisms of calcium oxalate about 0.02 mm. in diameter; resin in reddish-brown, angular masses; thin-walled parenchyma cells, isodiametric to elongated, many containing starch grains; tracheids very few or absent. White Pine Bark yields not more than 3 per cent. of ash." *N. F. IV.*

This bark was introduced into the N. F. IV for the purpose of making *Compound Syrup of White Pine* and *Compound Syrup of White Pine with Morphine.* The differentiation of these two syrups was a wise step in the last revision; but in our opinion it would have been wiser to have dropped *white pine* and all of the preparations; the syrup containing morphine has long been used and has no doubt contributed its share towards cultivating the morphine habit.

Whiting.—This is essentially the same as prepared chalk, being made by the pulverization and elutriation of crude chalk. It is used as a coarse paint, and for various purposes in the arts, for which calcium carbonate is requisite. *Paris white* is a variety of the same material.

Winter's Bark. *Wintera.*—The bark of *Drimys Winteri* Forst. *Cortex Winteranus. Ecorce de Winter, Cannelle de Magellan*, Fr. *Winter's Zimmt*, G. (Fam. *Magnoliaceæ.*)—For descriptions of tree, see *U. S. D.*, 16th edition. The tree is a native of the southern parts of South America, growing along the Strait of Magellan, and extending as far north as Chile. According to Martius, it is found also in Brazil. The bark of the tree was brought to England, in the latter part of the sixteenth century, by Captain Winter, who attended Drake on his voyage round the world, and while in the Strait had learned its aromatic and medicinal properties. Since this period, from time to time various barks have appeared in European commerce as *Winter's bark*, although not any that was the genuine bark. Among those in the London market was at one time the bark of *Cinnamodendron corticosum* Miers. (Fam. *Canellaceæ*), of Jamaica, which is pungent like true Winter's bark, but is of a much paler brown color, and resembles canella bark except in the absence of the chalky-white inner surface. More recently this bark has been replaced by the bark of *Croton Malambo* Karst. (Fam. *Euphorbiaceæ*), which resembles in color and thickness the bark of the Cinnamodendron, but has a bitter taste and a calamus-like flavor. For the description of a specimen which was in possession of George B. Wood many years since, see *U. S. D.*, 19th ed., p. 1696. P. N. Arata and F. Canzoneri (*P. J.*, June 14, 1890) describe a bark which they assert to be a genuine Winter's bark from the Strait of Magellan. From this they separated a volatile oil by distilling the bark with water, exhausting the distillate with petroleum, and distilling off the solvent. The crude oil, amounting to 0.64 per cent. of the weight of the bark employed, was a mixture of several substances. *Winterene*, $C_{15}H_{24}$, is the essential oil separated from this by fractional distillation. It is readily oxidized on exposure to the air, becoming yellow. The formula $C_{25}H_{40}$ was calculated from the ultimate analysis and vapor density, but the authors consider that the ready oxidizability of winterene and its analogy to similar essences point rather to the formula $C_{15}H_{24}$, which would place it in the group of sesquiterpenes, such as

cedrene, cubebene, etc. The presence of tannic acid and ferric oxide, according to Henry, serves to distinguish Winter's bark from *Canella alba*, with which it has often been confounded. The bark above described as commercial Winter's bark is destitute of both tannic acid and ferric oxide, and cannot therefore be the bark examined by Henry.

The bark of the *Drimys granatensis* L. f. (now regarded as identical with *D. Winteri* Forst.), has been imported into London under the name of *Merida coto*, and it has been stated that it contains *cotoin*. It occurs in short pieces of a yellowish-gray color, traversed longitudinally by hard cellular layers, which distinguish it at once from coto and paracoto bark. Its odor resembles that of true coto, but is more feeble. A careful chemical study of it by O. Hesse (*P. J.*, vol. iv) shows that it contains no cotoin, but a crystalline substance, $C_{18}H_{14}O_4$, to which the name of *drimin* was given. From the leaves Hesse obtained a wax alcohol, *drimol*, $C_{28}H_{58}O_2$. As *Drimys granatensis* L. f., is recognized as *D. Winteri* Forst., it is plain that Merida coto must be looked upon as a form of Winter's bark coming from Venezuela.

Winter's bark is a stimulant aromatic tonic, and was employed by Winter as a remedy for *scurvy*. It may be used in half-drachm (2.0 Gm.) *doses* for similar purposes with cinnamon or canella alba, but is scarcely known in the medical practice of this country. *Drimys chilensis* of De Candolle, growing in Chile, yields a bark having similar properties (Carson, *A. J. P.*, xix, 81); also *D. aromatica* F. Muell., of Australia. (*P. J.*, xxi.)

Wistaria. *Wistaria chinensis* DC. (*Kraunhia chinensis.*) (Fam. *Leguminosæ.*)—Ottow (*P. J.*, Oct., 1886) has obtained from this ornamental leguminous woody climber a crystalline poisonous glucoside, *wistarin*.

Withania. *Withania coagulans* Dun. (Stocks.) *Vegetable Rennet.* (Fam. *Solanaceæ.*)—This shrub, common in Afghanistan and East India, has the property of coagulating milk, and has been used for preparing a vegetable rennet ferment for making cheese. Sheridan Lea found upon examination that the substance which possesses the coagulating power is a ferment closely resembling animal rennet. The active principle is soluble in glycerin, and can be extracted from the seeds by this solvent; the extract possesses strong coagulating powers even in small amounts. Alcohol precipitates the ferment body from its solutions, and the precipitate, after washing with alcohol, may be dissolved again without having lost its coagulating powers. The active principle of the seeds will cause the coagulation of milk when present in very small quantities, the addition of more of the ferment simply increasing the rapidity of the change. The coagulation is not due to the formation of acid by the ferment. If some of the active extract be made neutral or alkaline, and added to neutral milk, a normal clot is formed, and the reaction of the clot remains neutral or faintly alkaline. The clot formed by the action of the ferment is a true clot, resembling in appearance and properties that formed by animal rennet, and is not a mere precipitate. Lea prepared an active extract, applicable for cheese making purposes, by grinding the dry seeds very finely in a mill, and extracting them for twenty-four hours with such a volume of 5 per cent. sodium chloride solution that the mass is still fluid after the absorption of water by the fragments of the seeds as they swell up. From this mass the fluid part may be readily separated by using a centrifugal machine (such as is used in sugar refining), and it can then be easily filtered through filter paper; without the centrifugal machine the separation of the fluid from the residue of the seeds is tedious and imperfect; forty grammes of the seeds treated as above, with 150 mils of 5 per cent. sodium chloride solution, gave an extract of which 0.25 mil clotted 20 mils of milk in twenty-five minutes, and 0.1 mil clotted a similar portion of milk in one hour. When added in these proportions the curd formed is quite white. The presence of the coloring matter is, however, perhaps on the whole unimportant, since even if a larger quantity of the ferment extract is added in order to obtain a very rapid coagulation, the coloring matter is obtained chiefly in the whey, the curd being white; by adding sufficient common salt to make the percentage up to 15 per cent., and alcohol up to 4 per cent., the preparation would retain its activity very well. (*P. J.*, 1884, 606.)

Wrightia. *Wrightia zeylanica* R. Br. (*W. antidysenterica* R. Br.) (Fam. *Apocynaceæ.*)—Under the names of *Conessi bark, Tellicherri bark*, and *Codaya pala*, a spongy, rusty-colored, bitter bark of this apocynaceous tree was formerly used in Europe as a remedy in *dysentery* and *diarrhea*, and is said still to be largely employed by the native practitioners of India. Stenhouse obtained from the seeds, besides a fixed oil which they contain in large quantity, a non-crystalline alkaloid, called by him *wrightine*, which seems to be the same substance previously described by Hains under the name of *conessine*. (*P. J.* (2), vi, 432.) The alkaloid conessine is now a commercial product prepared by Merck, and the formula $C_{24}H_{40}N_2$ is given it. It occurs in delicate, white, interlaced masses of crystals, melting at 121° C. (249.8° F.), sparingly soluble in water, readily so in alcohol. A small quantity rubbed with a few drops of concentrated sulphuric acid affords on the addition of nitric acid a golden and finally orange-yellow color. We are not aware that the medicinal properties of this have been investigated.

A species of the allied genus *Holarrhena* (*H. africana* A. DC.), is stated by German missionaries to be used in parts of tropical Africa in *dysentery*. Polstorx and Schirmer (*Ber. d. Chem. Ges.*, 1886, 78) prepared the alkaloid both from *Holarrhena africana* and from *Wrightia zeylanica*, finding it to be identical in the two cases. When oxidized by iodic acid in sulphuric acid solution, conessine is changed to *oxyconessine*, $(C_{12}H_{20}NO.)_2$.

Wurrus.—Under the name of *Vars, Wars*, or *Wurrus*, a powder somewhat similar to kamala has been used as an anthelmintic in Southern Arabia, and exported into commerce from Aden. It is believed to be the product of *Flemmingia Grahamiana* W. et Arn. (Fam. *Leguminosæ.*) (*P. J.*, Sept., 1887.) It is composed of cylindrical or subconical grains, 170 to 200 mm. long by 70 to 100 broad, with oblong resin cells arranged perpendicularly in three or four tiers.

Xanol.—This is a *caffeo-sodium salicylate*. The salicylic radical is said to be obtained from *natural wintergreen oil*. It forms a very soluble white powder which is decomposed by acids. It is used as a vasomotor heart tonic and diuretic.

Xanthium.—Guichard believes that he has found an alkaloid in the *X. spinosum* L. (*P. J.*, vii, 249.) In the *Xanthium Strumarium* L., *Cocklebur* or *Clotbur*, which is common both in Europe and in America, A. Zander believes that he has found a glucoside, *xanthostrumarin*. M.

V. Cheatham thinks that there is a second active principle. (See *A. J. P.*, vol. xi, 271; vol. xiv, 134.) Clotbur is stated to be an active styptic, both local and general. *Dose*, of the fluidextract, from one to two fluidrachms (3.75–7.5 mils).

Xanthorrhiza. *Yellow-root. Shrub Yellow-root. Xanthorrhiza apiifolia* L'Her. (Fam. *Ranunculaceæ.*)—This is a low shrub, with a horizontal rhizome, which sends off numerous suckers. The stem is simple, about 5 mm. thick, with a smooth bark and bright yellow wood. The leaves, are compound, consisting of several ovate-lanceolate, acute, doubly serrate leaflets, sessile upon a long petiole, which embraces the stem at its base. The flowers are small, purple, and, disposed in long, drooping, divided racemes, placed immediately below the first leaves. Yellow-root grows from Southern New York to Georgia and west to Kentucky. It flowers in April. The root was formerly in the Secondary List of the U. S. Pharmacopœia, but the bark of the stem possesses the same virtues. The root is from 7 cm. to 1 dm. in length, and about 12 mm. thick near the stem. It shrinks somewhat in drying, and, as found in commerce, is in slender pieces of various lengths, wrinkled longitudinally, with a light yellowish-brown, easily separable epidermis, a thick, hard, bright yellow woody portion, and a very slender central pith. It is inodorous, and of a simple but extremely bitter taste. It imparts its color and taste to water. The infusion is not affected by ferric salts. J. Dyson Perrins found *berberine* in it. (*P. J.*, May, 1862.) Samuel S. Jones believed that he had proved the existence in the drug of a second alkaloid. (*A. J. P.*, vol. xvi, 1861.) *Xanthorrhiza* possesses properties closely analogous to those of calumba, quassia, and other simple tonic bitters, and may be used for the same purposes and in the same manner. Woodhouse employed it in the *dose* of forty grains (2.6 Gm.).

Xanthorrhœa Resins. *Gum Acaroides. Gum Acroides. Grass-tree Gum. Botany Bay Gum.*—Yellow and reddish resinous substances, the products of *Xanthorrhœa hastilis* R. Br. and *X. australis* R. Br. (fam. *Liliaceæ*), have been introduced into England from Australia. They are obtained by spontaneous exudation from the stems of the plants, which are usually shrubs. The *yellow variety* (from *X. hastilis*) is in tears, in flattish pieces having on one side the mark of the stem, or in masses of various size and irregular shape. It has a reddish-yellow color, resembling gamboge when broken, and when heated emits a fragrant odor like that of Tolu balsam. It contains resin, cinnamic and benzoic acids, and a trace of volatile oil, and may therefore be ranked among the balsams. When heated with nitric acid, it yields a large proportion of picric acid. In medicinal properties it is said to bear a close resemblance to storax and the balsam of Tolu. A tincture, made in the proportion of two ounces to a pint of alcohol, may be given in the *dose* of one or two fluidrachms. The *red variety* (from *X. australis* R. Br.) resembles dragon's blood in color, and appears to be analogous to the other variety in properties. (See *A. J. P.*, 1881; also *A. J. P.*, vol. xv, and *D. C.*, 1895, 83.) These resins have been introduced as a shellac substitute in varnish making.

Xanthoxylum Berries. *Xanthoxyli Fructus. N. F. IV. Prickly Ash Berries.*—"The fruit of *Zanthoxylum americanum* Miller (*Northern Prickly Ash*), or *Zanthoxylum Clava-Herculis* Linné (*Southern Prickly Ash*) (Fam. *Rutaceæ*)." *N. F. IV.*

Prickly ash berries were introduced in the N. F. IV to be used as an ingredient in *compound fluidextract of stillingia* N. F. IV, made with a menstruum of 25 volumes of glycerin, 50 volumes of alcohol and 25 volumes of water, finishing with diluted alcohol. The berries are described as "Capsules with short stalks (*X. americanum*) or without stalk (*Z. Clava-Herculis*); when fresh, ellipsoidal, fleshy, gray-brown, when dry, dehiscent; carpels two, convex, summit short pointed; seeds one or two oblong, black, shining, and wrinkled from drying. The carpels have a pungent, warm, aromatic taste and on chewing leave a tingling sensation on the tongue; when breathed upon they emit a faintly aromatic odor resembling that of citral. Prickly Ash Berries yield not more than 7 per cent. of ash." *N. F. IV.*

Xylene. *Xylol. Xylène*, Fr. *Xylol*, G. $C_6H_4(CH_3)_2$.—There are three isomeric hydrocarbons of this name, the ortho-, meta-, and para-xylene respectively, all contained in coal tar. A mixture of them was first extracted from naphtha by Hugo Müller, and was brought forward by Zuelzer as a specific in *smallpox*, but is useless. (*P. J.*, 1872, 623.) It is largely used as a solvent by microscopists.

Xylochloral.—A compound of chloral and *xylose* (*wood sugar*, $C_6H_{10}O_5$), analogous with chloralose. It forms colorless soluble scaly fragments fusing at 132° C. (269.6° F.). It has been used as a hypnotic. *Dose*, ten to fifteen grains (0.6–1.0 Gm.).

Xylenol Orthosalicylate. *Orthoxylenol Salol.* $C_8H_9C_7H_5O_3$.—A neutral white powder devoid of odor and taste. It is employed as an internal antiseptic and antirheumatic. The metaxylenol salol is used for the same purposes as the ortho compound. *Dose*, two to six grains (0.12–0.36 Gm.).

Yeast. *Cerevisiæ Fermentum Compressum*, N. F. *Compressed Yeast. Fœx medicinalis. Hefe, Bierhefe*, G. *Levure*, Fr.—The ferment obtained in brewing beer, and produced by *Saccharomyces* (*Torula* Turpin) *cerevisiæ* Meyen, was dismissed from the U. S. Pharmacopœia in 1880, from the British in 1898. Two well-marked varieties of the *Saccharomyces cerevisiæ* have been recognized. The one is the most active at the ordinary temperature (16°–20° C., 60.8°–68° F.), and carries through its fermentative work in from three to four days; the other works at a lower temperature (6°–8° C., 42.8°–46.4° F.), and the fermentation is much slower. The first placed in a saccharine liquid is carried by the carbon dioxide which it liberates to the surface of the liquid, where it continues its activity; it is, therefore, known as a *surface* or *top yeast*. The second, on the contrary, is not carried up, and rests during its entire activity on the bottom of the fermenting vessel, and is hence called a *bottom yeast*. Two quite distinct methods of beer brewing are practised, depending upon the use of the one or the other of these varieties of yeast. (For fuller information as to the nature of *yeast* and its conditions of culture and activity, see Sadtler's *Industrial Organic Chemistry*, Philadelphia, 3d ed., 1900, 185 *et seq.*)

Yeast is a flocculent, frothy, somewhat viscid semi-fluid, of a dirty yellowish color, a sour vinous odor, and a bitter taste. Exposed to a moderate heat it loses its liquid portion, becomes dry, hard, and brittle, and may in this state be preserved for a long time, though with the loss of much of its

peculiar power. *Yeast cakes* are made by putting yeast into sacks, washing it with water, then submitting it to pressure, and ultimately drying it; *compressed yeast*, the undried product, is now largely used.

Yeast is insoluble in alcohol or water. Its ultimate composition, according to Schlossberger (*Ann. Ch. Ph.*, 51, 199), is carbon 49.9 per cent., hydrogen 6.6 per cent., nitrogen 12.1 per cent., and oxygen 31.4 per cent. Its proximate constituents are albuminoids, cellulose, fats, and resinous substances.

The chief function of yeast is the inducing of the vinous fermentation, in which are produced alcohol and carbon dioxide, and various other substances in smaller or larger proportions. Pasteur has shown that while from 94 to 95 per cent. of the sugar decomposes into ethyl alcohol and carbon dioxide, the other 5 or 6 per cent. decomposes by secondary reactions, yielding glycerin from 2.5 to 3.6 per cent. and succinic acid from 0.4 to 0.7 per cent. The higher homologues of ethyl alcohol are also produced in small amount, forming fusel oil or raw spirit.

Yeast consists of numerous cells, irregular, roundish, or cylindrical in shape, separate, joined into rows, or budding one from the other. It is most probable that the yeast plant is the mycelium, or early vegetative stage, of more than one species of mucor or mould; and some authorities recognize various species of the yeast fungus. The name *Torula cerevisiæ* was first given to the yeast plant, which was subsequently called *Mycoderma vini;* Reess, in his elaborate work (*Alkoholsgährungspilze*, Leipsic, 1870), made a distinct genus of it, *Saccharomyces*, including many species.

The wine-producing yeasts are varieties of the species *Saccharomyces ellipsoideus.*

Compressed Yeast is official in the N. F. IV under the title *Cerevisiæ Fermentum Compressum.* It is described as "the moist, living cells of *Saccharomyces cerevisiæ* Meyen (Fam. *Saccharomycetaceæ*) or of other species of *Saccharomyces*, combined with a starchy or absorbent base. White or yellowish-white, soft and easily broken masses, having a characteristic, slightly sour odor, and not more than a faintly acid reaction to litmus. When examined under the microscope, numerous oidium and mycoderma cells and starch grains are visible. Compressed yeast must not be used unless fresh, and free from mildew and musty or foul odors." *N. F.*

According to Albert Buchner and Rapp, a dried yeast which retains its activity on keeping is obtained as follows: The yeast is freed from water as much as possible by expression, immersed in acetone and rubbed through a sieve. The acetone is decanted, renewed, again decanted, and the residue collected by the aid of a suction filter, then treated with ether for three minutes, and this removed in the same way, after which the the yeast is spread out to dry, the drying being completed at a temperature of 45° C. (113° F.). Dried yeast, so obtained, is an almost white powder. (*Ph. Centralh.*, 1903, 36.)

According to Casagrandi, *Saccharomyces ruber*, previously discovered by Demme, produces a *red yeast* which ferments glucose very readily, developing a red pigment. This saccharomyces was found pathogenic to various animals, and when put into milk so modified that liquid as to convert it into a pronounced intestinal irritant. (*P. J.*, Jan., 1898.) A number of yeasts are used in China and Java whose fundamental plants are different from those of the European yeast. See *P. J.*, vol. xlvii.

Yeast has been very widely employed, not only as a folk remedy, but also by the medical profession, in the treatment of various infectious conditions, especially of the skin. On the whole, there is strong clinical evidence of its usefulness in *furunculosis, acne* and the like. There is no generally accepted explanation of its mode of action. Certain investigators have believed it to exercise a direct bactericidal effect, but Tsuru (*W. K. R.*, 1909) found that this action was only exerted by growing yeast, and believed that the effect was due to the production of alcohol and various acids, during the process of fermentation. Abraham (*Monatsschrift fur Geburtsh. u. Gyn.*, 1910, No. 1) dissents from this conclusion, because he found that living yeast exercised an antibacterial effect, even in the absence of sugar. Even although yeast possessed active germicidal properties, this could not explain the benefit which has followed its internal administration. Some writers believe that this action is due to the high nuclein content, the latter acting as a stimulant to the formation of leucocytes. (See p. 1512.)

A possible explanation of the therapeutic benefit of yeast has been suggested by the experiments of Walzou and Sacharow, who found that it increased the opsonic index of dogs for staphylococci and streptococci. Plantier (*S. M.*, 1907) has had excellent results with the local application of yeast in the treatment of *burns.* He spreads a thick paste of the ferment upon strips of gauze which are applied to the denuded area, being renewed every two or three days. The preparation which is generally preferred by clinicians is the semi-liquid *brewer's yeast.* This has been employed internally in *doses* of from one to two ounces (30 to 60 mils) several times a day. It has also been used locally, especially in vaginal infections.

Of the N. F. compressed yeast from one to three teaspoonfuls (4–11 Gm.) may be given three times a day; of the liquid, brewer's yeast, two to four ounces (60–120 mils).

Dried yeast has been much used in France and it is probable that the ordinary *yeast cake* of American bakers may well be substituted for yeast.

A large number of preparations of yeast have been placed upon the market under various trade names. Among these the following may be mentioned: *Ceridin (cerolin). Dose,* one and a half to three grains (0.1 to 0.2 Gm.). *Bajuvarin* is a preparation of yeast which is used both internally and locally by veterinarians. *Fermentine* is a preparation of yeast containing benzoin, used principally for local application. *Fermocyl.* A mixture of dried yeast, pancreas and sodium phosphate, marketed in the form of tablets, each corresponding to about 30 grains (2 Gm.) of the fresh yeast. Used in diabetes. *Furunculin. Dose,* ten to thirty grains (0.65–2 Gm.). *Levuretin, Levurin,* and *Leuvurinose* are proprietary forms of dried beer yeast; any of them may be given in doses of one drachm (3.9 Gm.). *Mycodermin.* Marketed only in pills. *Dose,* 2 to 4 pills. *Trygase. Dose,* one teaspoonful. *Zymin* is a dried yeast which is marketed either as a powder, intended for external use, or in the form of tablets each of which contains fifteen grains (1 Gm.).

Xerase. N. N. R. 1917. This is stated to be a mixture of yeast and kaolin with glucose and salts. This is a yellowish-gray powder, asserted to possess not only absorbent but also bactericidal powers. It is intended for local application, especially in *gonorrhea* of women.

Cerolin. N. N. R. 1917. A fatty substance derived from yeast, asserted to represent the specifically active constituent of yeast. It is a yellowish to a brownish semifluid with an odor resembling that of yeast. It is used in the treatment of *furunculosis, acne* and *scurvy,* possessing also a laxative action. *Dose,* one and a half to five grains (0.096–0.32 Gm.). Pills of cerolin, each containing one and one-half grains (0.1 Gm.), are also on the market.

Yohimbine.—This is an alkaloid which is obtained from the bark of *Corynanthe Yohimbi* Schum., a rubiaceous tree growing in the Southern Cameroons district in Africa. The bark comes into commerce in flattened or slightly quilled pieces 75 cm. long to 4 to 8 mm. thick, with an external corky layer of a gray-brown color covered with isolated lichens. It shows numerous longitudinal and transverse fissures like some old specimens of cinchona bark. The transverse fracture is of a uniform yellowish-brown color, and presents short, soft fibers like rough velvet. The taste is bitter.

The alkaloid has been obtained in white needles melting at 234° C. (453.2° F.) and having the composition $C_{23}H_{32}N_2O_6$.

The salt of this base that is ordinarily used is the hydrochloride, being preferable on account of its solubility and high percentage of the alkaloid.

It was originally investigated by Oberwarth and Loewy (*V. A. P. A.,* cliii, and *B. K. W.,* No. 42, 1900), who found it to be in animals and also in man a very active excitant to the sexual organs and functions. On the other hand, Kravkoff, as the result of experiments upon the lower animals and upon man, concluded that it has no aphrodisiac effects and frequently produces nausea, salivation, irritability, and other disagreeable results.

Muller (*A. I. P. T.,* 1907, p. 65) found that *yohimbine,* in small doses stimulated, and in large doses depressed, the respiratory center. If lethal doses are given the heart continues beating after the respiration has ceased. Small doses have little effect upon the blood pressure, but moderate-sized doses caused a slight rise in the blood pressure with local dilatation of the vessels of the pelvic organs. He believes that its aphrodisiac action is due to an increase in the excitability of the lower centers in the spinal cord. On the other hand, many authors believe that its effect is due to the hyperemia produced. Toff (*D. M. W.,* 1904) has found it useful because of this effect in scanty or *irregular menstruation.*

It has been used by numerous clinicians in *neurasthenic impotence,* with reports which are generally favorable to its influence. (For literature, see *M. R.,* 1901, 1902.) It is said to be of no value when the impotence depends upon organic nerve trouble, and to be harmful when it is caused by chronic inflammatory disease of the sexual organs or of the prostate gland. *Dose,* of the hydrochloride, 0.005 Gm. (one-twelfth grain), either in tablet or solution, three or four times a day. Yohimbine has also been employed in a 1 per cent. solution hypodermically.

Zea. *N. F. IV (U. S. P. VIII). Corn Silk. Stigmata Maydis. Filament de Mais,* Fr. *Maispistille,* G.—"The fresh styles and stigmas of *Zea Mays* Linné (Fam. *Gramineæ*)." N. F.

This drug is the so-called "silk" of the ear of ordinary Indian corn or maize, cultivated in the warmer temperate and subtropical countries of the world. It consists of "slender filaments from 10 to 20 cm. in length, and about 0.4 mm. in diameter; of a light green, purplish-red, yellow or light brown color; stigmas bifid, the segments very slender, frequently unequal and from 0.4 to 3 mm. in length. Under the microscope, the styles are seen to consist for the most part of parenchyma and two parallel, vascular bundles with narrow, spiral or annular tracheæ; the epidermal cells are rectangular, many of these being extended into multicellular hairs, the latter being from 0.2 to 0.8 mm. in length, the basal portion consisting of two to five united cells, the upper portion being usually unicellular; the cells of the hairs are rich in cytoplasm and usually contain a small, spherical nucleus; the purplish-red styles contain a purplish-red cell sap. Digest a small portion of the fresh styles and stigmas in diluted alcohol and filter; a pale purplish-red solution is produced, separate portions of which, on the addition of acids, become distinctly purplish or yellowish-red; on the addition of alkalies, green; on the addition of ferric chloride T.S., olive-green changing to greenish-brown; and on the addition of an aqueous solution of alum, bluish or purplish, the color being quite permanent." *N. F.* Rademaker and Fischer (*A. J. P.,* 1886, p. 369) determined the presence of 2.25 per cent. of *maizenic acid* in dried corn silk. It was first described, however, by Vautier. It is freely soluble in water, alcohol and ether, but insoluble in benzin. Rademaker and Fischer found, in addition to the acid, fixed oil, resin, chlorophyll, sugar, gum, extractive, albuminoids, phlobaphene salt, cellulose and water.

Used as a mild stimulant diuretic, useful in *acute* and *chronic cystitis* and in the bladder irritation of *uric acid* and *phosphatic gravel.* It has also been employed in *gonorrhea,* and has been affirmed by Landreux to be a useful diuretic and even cardiac stimulant in the *dropsy of heart disease.* It probably is, however, of little value.

Concerning the activity of *maizenic acid* we have little definite knowledge, but it probably represents whatever physiological power the drug possesses; it has been given in the *dose* of one-eighth of a grain (0.008 Gm.).

Corn silk was official in the U. S. VIII but dismissed from the U. S. IX. It was introduced in the N. F. IV. The fluidextract of zea N. F. is made with a menstruum of diluted alcohol.

Dose, one to three drachms (3.9–11.6 Gm.).

Zebromal.—The *dibrom-cinnamic-ethyl-ester,* $C_6H_5.CHBr.CHBr.COOC_2H_5$, occurs as a white crystalline powder, soluble in alcohol with the fatty oils, but not in water. It has been suggested by Ellinger and Kotake (*A. E. P. P.,* 1911, lxv, p. 87) as a substitute for the alkaline bromides in *epilepsy,* but we know of no clinical reports of its efficacy.

Zedoary. *N. F. IV. Zedoaria. Radix Zedoariæ. Rhizoma Zedoariæ,* P. G. *Zedoarie,* Fr. *Zitterwurzel,* G.—"The dried rhizome of *Curcuma Zedoaria* (Bergius) Roscoe (Fam. *Zingiberaceæ*)." *N. F.* There are two kinds of zedoary, the long and the round, distinguished by the old official titles of *radix zedoariæ longæ* and *radix zedoariæ rotundæ.* Both kinds come from the East Indies. The *long zedoary* is in slices, from 2.5 to 7.5 cm. in length, and from 1 to 2.5 cm. thick, obtuse at the extremities and exhibiting the remains of the radical fibers. The *round* is commonly seen in communities, and is "usually cut into transverse rounded sections, twisted and wrinkled, from 1 to 4 cm. in diameter, and from 5 to 10 mm. in thickness; externally grayish-brown, hairy, rough, with few root scars;

transverse surface pale reddish to gray-brown; a distinct, dark circular endodermis, which is from 2 to 5 mm. in width, separates the cortex; the stele contains numerous, orange-colored resin cells and irregularly distributed, lighter colored wood bundles which are fewer in the cortex; fracture short, somewhat mealy and waxy. Odor aromatic, camphor-like; taste aromatic, warm, slightly bitter. Under the microscope, sections show a thick cork, a thin epidermis with numerous characteristic hairs, thick-walled, one- to six-celled, up to 1 mm. in length and often thicker in the middle than at the base; the parenchyma of the cortex and of the central cylinder rich in starch; secretion cells isodiametric with suberized walls, contents colorless or yellowish; the endodermis of small, thin-walled quadratic cells, the fibro-vascular bundles collateral, more numerous in the central cylinder and nearer the endodermis; few bast fibers in the cortex and no crystal cells. The powder contains numerous starch-grains which are ovoid, from 0.02 to 0.07 mm. in length and from 0.007 to 0.03 mm. in thickness, having the point of origin of growth in the smaller end of the grain; numerous characteristic, thick-walled hairs; rich in parenchyma; very few bast fibers; no calcium oxalate crystals or stone cells. Zedoary yields not more than 7 per cent. of ash." *N. F.*

Zedoary yields a volatile oil, when distilled with water, and contains a pungent soft resin and bitter extractive.

Zedoary was introduced into the N. F. IV and is used as an ingredient in *bitter tincture of zedoary, antiperiodic pills, antiperiodic pills without aloes, bitter tincture, antiperiodic tincture and antiperiodic tincture without aloes.*

Zedoary is a warm, stimulating aromatic, useful in flatulent colic and debility of the digestive organs. It is rarely employed, as it produces no effects which cannot be as well or better obtained from ginger. The *dose* is from ten grains to half a drachm (0.65–2.0 Gm.).

Zerechtit. *Tschuking. Landtia Schimperi* Benth. and Hook. (*Ubicea Schimperi* J. Gay *Arctotis Schimperi* O. Kze.)—The leaves, flowers and fruit of an Abyssinian composite. (See *Proc. A. Ph. A.*, xxvi, 228.)

Zerumbet. *Cassumuniar.*—Under these names an East Indian root was formerly used, having some analogy in sensible and medicinal properties to ginger, and ascribed to the *Zingiber Zerumbet* of Roscoe. By some authors the zerumbet has been erroneously confounded with the round zedoary. Geiger describes it as in pieces of the size of a fig or larger, externally grayish-brown and wrinkled, internally yellowish, hard and tough, of a biting, aromatic taste and a spicy odor.

Zimphen. *Sodium Metaoxycinnamate.*—This forms yellow crystals. Soluble in alcohol and but sparingly soluble in water. It is employed internally as a general antiseptic. *Dose,* eight grains (0.5 Gm.) before meals.

Zinc and Potassium Cyanide. *Zinci et Potassii Cyanidum.* $K_2Zn(Cn)_4$.—Made by adding zinc cyanide to solution of potassium cyanide, evaporating and crystallizing. The salt possesses a sweet and metallic taste and is used for the same purposes as zinc cyanide in from one-eighth to one-half grain (0.008–0.032 Gm.) *doses.*

Zinc Borate. *Zinci Boras.* $ZnB_4O_7 + 7H_2O$.—Prepared by mixing an aqueous solution of zinc sulphate (1 in 10) with one of borax (1 in 25), and collecting the precipitate. Used as an antiseptic dusting powder.

Zinc Bromide. *Zinci Bromidum. U. S. VIII. Zincum Bromatum. Bromure de Zinc,* Fr. *Bromzink, Zinkbromid,* G. *Bromuro zincico,* Sp. $ZnBr_2 = 225.21$.—"It should contain, when anhydrous, at least 97 per cent. of pure Zinc Bromide, and should be kept in small, glass-stoppered bottles." *U. S. VIII.*

Zinc bromide may be made either by the direct combination of zinc and bromine, or by dissolving zinc in a solution of hydrobromic acid. L. Lyons proposes to make this salt by dissolving potassium bromide and crystallized zinc sulphate, each, in the smallest quantity of hot water and mixing while hot. When the mixture has cooled, twice its bulk of alcohol is added and the whole filtered through asbestos to separate the potassium sulphate. The filtrate is then evaporated to dryness.

It is "a white, or nearly white, granular powder; odorless, having, even in dilute solutions, a sharp, saline and metallic taste. Very deliquescent. Readily soluble in water and alcohol. When heated to 394° C. (741.2° F.), the salt fuses, and, with a careful increase of heat, may be sublimed in the form of needle-shaped prisms. Its aqueous solution gives a slightly acid reaction with blue litmus paper." *U. S. VIII.*

It responds to the tests for zinc and for hydrobromic acid. The absence of iodides may be shown by adding to 10 mils of the aqueous solution of the salt (1 in 20) 1 mil of chloroform, then chlorine water (which has been diluted with an equal volume of water), cautiously introduced, drop by drop, with constant agitation, the liberated bromine will dissolve in the chloroform, imparting to it a yellow to orange color, free from any violet tint (absence of *iodide*).

"The aqueous solution of the salt (1 in 20), to which sufficient hydrochloric acid has been added to insure a clear solution, should not respond to the Time-Limit Test for *arsenic, cadmium, lead,* and *copper* (see U. S. P. VIII, Test No. 121); in applying this test the addition of ammonia water should be omitted. Another portion of this aqueous solution should not be rendered turbid by the addition of barium chloride T.S. (absence of *sulphate*). Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic.*" *U. S. VIII.*

Zinc bromide is capable in excessive doses of acting as an irritant poison. It has been commended in *epilepsy,* but is of no value.

Dose, one to two grains (0.065–0.13 Gm.).

Zinc Cyanide. *Zinci Cyanidum.* $Zn(Cn)_2$.—This cyanide is precipitated as a white insoluble powder, by adding cautiously, until it ceases to produce a precipitate, a recently filtered solution of potassium cyanide to a solution of zinc sulphate. It is used in Germany as a substitute for hydrocyanic acid, and is said to be anthelmintic. It has been recommended by Lashkevich in *cardiac neuroses* in doses of from one-tenth to one-eighth grains (0.006–0.008 Gm.) three times a day. It has been employed in *epilepsy, chorea* and *neuralgia,* in several *painful affections of the stomach* and in the *colics* attendant on *difficult menstruation.* The *dose* is a quarter of a grain (0.016 Gm.), gradually increased to a grain and a half (0.096 Gm.), given in mixture. It is official in the French Codex.

Zinc Ferrocyanide. *Zinci Ferrocyanidum.* $Zn_2Fe(Cn)_6 + 3H_2O$.—Formed by double decomposition between hot solutions of potassium ferrocyanide and zinc sulphate. It is precipitated as

a white powder. It has similar medicinal properties to those of the cyanide, and is used in the same diseases. The *dose* is from one to four grains (0.065–0.26 Gm.), given in pill. (See *Zinc Cyanide*, p. 1671.)

Zinc Iodide. *Zinci Iodidum. U. S. VIII. Zincum Iodatum. Iodure de Zinc*, Fr. *Zinkjodid, Jodzink*, G. $ZnI_2 = 319.21$.—"It should contain, when anhydrous, not less than 98 per cent. of pure Zinc Iodide, and should be kept in small, glass-stoppered bottles protected from light." *U. S. VIII.*

This iodide may be formed by digesting an excess of zinc, in small pieces, with iodine diffused in water. Combination takes place and, by evaporation, a deliquescent, very soluble saline mass is obtained, having a metallic styptic taste, resembling that of zinc sulphate. It may also be obtained by heating in a flask a mixture of 20 parts of zinc and 170 of iodine, and subliming into a vial. Thus prepared, it is in the form of white needles. This salt is very liable to spontaneous decomposition.

Properties.—It is "a white, or nearly white, granular powder; odorless, and having a sharp, saline and metallic taste. Very deliquescent, and, upon exposure to air and light, becoming brown from liberated iodine. Readily soluble in water, alcohol, or ether. When heated to about 446° C. (834.8° F.), the salt fuses to a colorless liquid, and at a higher temperature sublimes, forming quadratic needles, while a small part is decomposed and leaves a residue of zinc oxide. Its aqueous solution reddens blue litmus paper. An aqueous solution of the salt (1 in 20) yields a white gelatinous precipitate with potassium ferrocyanide T.S., and a pure white precipitate with ammonium sulphide T.S. With silver nitrate T.S. it yields a pale yellow precipitate, insoluble in ammonia water; with mercuric chloride T.S., a red precipitate, soluble in potassium iodide T.S. The aqueous solution of the salt (1 in 20), to which sufficient diluted hydrochloric acid has been added to insure a clear solution, should not respond to the Time-Limit Test for *arsenic, cadmium, lead,* and *copper* (see U. S. P. VIII, Test No. 121); in applying this test the addition of ammonia water should be omitted. Another portion of the aqueous solution should not be rendered turbid upon the addition of barium chloride T.S. (absence of *sulphate*). If ammonium carbonate T.S. be added to the aqueous solution of the salt (1 in 20), a pure white precipitate will form, which should redissolve completely in an excess of the reagent. Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. VIII, Test No. 17). If 1 Gm. of Zinc Iodide be mixed with 5 Cc. of distilled water, and sufficient ammonia water be added to redissolve the precipitate formed, followed by a solution of 1.5 Gm. of silver nitrate in 10 Cc. of water, then, after shaking and filtering, the filtrate should not be rendered more than slightly turbid by the addition of an excess of nitric acid (limit of *chloride*). If 0.5 Gm. of dry Zinc Iodide be dissolved in 20 Cc. of water, and if 35 Cc. of tenth-normal silver nitrate V.S., 5 Cc. of nitric acid, and 3 Cc. of ferric ammonium sulphate T.S. be added, and the mixture well shaken, then the addition of not less than 3.4 Cc. nor more than 4 Cc. of tenth-normal potassium sulphocyanate V.S. should be required to give a permanent reddish-brown tint to the solution." *U. S. VIII.*

Zinc iodide was proposed by Barlow as an alterative remedy in *chorea, scrofula* and *hysteria* (*M. T. G.*, Nov., 1853), but has failed to come into general use. The best form of administration is in *syrup*, to protect it from change. (See p. 1353, *U. S. D.*, 19th ed.) Zinc iodide has been used as an external application. A solution containing from one to two grains (0.065–0.13 Gm.) to the fluidounce (30 mils) of water has been used as an astringent injection in *gonorrhea.*

Dose, one-half to two grains (0.032–0.13 Gm.).

Zinc Lactate. *Zinci Lactas.* $Zn(C_3H_5O_3)_2 + 3H_2O$.—This salt is used by Herpin in *doses* of two grains (0.13 Gm.), three times a day, gradually increased to ten grains (0.65 Gm.) a day, as a substitute for zinc oxide in *epilepsy.* For its physical properties and methods of preparation see 16th edition *U. S. D.*

Zinc Permanganate. *N. N. R.* 1917. *Zinci Permanganas. Zinkpermanganat, Uebermangansaures Zink*, G. $Zn(MnO_4)_2 + 2H_2O$.—Made by precipitating barium permanganate with zinc sulphate, using exact molecular proportions. It forms almost black deliquescent crystals, giving off oxygen even more readily than does potassium permanganate. It is incompatible with peroxides, acids, ammonia and hypophosphites, and must not be triturated with organic substances. It is used as an astringent and antiseptic application.

Zinc Peroxide. *Zinc Perhydrol. Zinconal.*—A mixture stated to contain equal parts of *zinc peroxide* and zinc oxide, has been introduced as an antiseptic dusting powder in the treatment of *wounds* and *ulcers.* It is a white insoluble powder and its value appears to depend upon the slow formation of hydrogen dioxide. It may be used either in the form of a dusting powder or as an ointment in strengths of 25 to 50 per cent.

Zinc Phosphate. *Zinci Phosphas. Trizincic Orthophosphate.* $Zn_3(PO_4)_2 + 4H_2O$.—Barnes, of London, has brought forward this salt of zinc as having special advantages over other salts of the same metal in the treatment of *nervous diseases*, peculiarly useful in the *insanity* occurring in the convalescence from fevers, in which he associates it with quinine, and in *epilepsy* attended by *disorder of the uterine functions.* Zinc phosphate may be prepared by the mutual reaction of zinc sulphate and an alkaline phosphate. Zinc phosphate is a white powder, insoluble in water but soluble in acids.

Zinc Phosphide. *Zinci Phosphidum. U. S.* 1890. $Zn_3P_2 = 258.19$.—According to Hager, *zinc phosphide* was first prepared by Marggraf in 1740. It was formerly made by fusing, in a bath of iron filings, 74 parts of pure zinc, and adding gradually, in small pieces, 26 parts of dry phosphorus. This process gives good results only in small quantities (10 to 20 Gm.). A more recent process is to pass vapors of phosphorus in a current of dry hydrogen over fused zinc. The product is a spongy, gray mass, of metallic appearance, containing rhomboidal crystals, and when powdered resembling somewhat reduced iron. The particles of metallic zinc should be separated. Its sp. gr. is 4.72. "Zinc phosphide should be kept in small, glass-stoppered vials." *U. S.*, 1890.

It occurs as "a gritty powder of a dark gray color, or crystalline fragments of a dark, metallic luster, and having a faint odor and taste of phosphorus. In contact with the air it slowly emits phosphorous vapor. Insoluble in water or alcohol. Soluble in diluted hydrochloric or sulphuric acid with evolution of hydrogen phosphide. When

strongly heated, with exclusion of air, it melts and finally sublimes. When heated in air, it becomes oxidized to zinc phosphate. If 0.5 Gm. of zinc phosphide be dissolved in 15 Cc. of diluted hydrochloric acid, heat being applied to expel all of the hydrogen phosphide gas, a clear solution should result, leaving no residue (absence of *insoluble impurities*). A portion of this solution should yield a pure white precipitate with potassium ferrocyanide test-solution (absence of *iron* or *copper*); or with ammonium sulphide test-solution (absence of *lead* or *copper*). If another portion of this solution be mixed with an equal volume of hydrogen sulphide test-solution, no color or turbidity should appear (absence of *arsenic, cadmium, lead, copper,* etc.)." For a method of assay of zinc phosphide, see *N. R.*, June, 1879.

It has been proved by direct experiment upon animals, as well as by clinical experience, that zinc phosphide affects the system physiologically and therapeutically in exactly the same manner as does phosphorus, and it is employed in medicine as a substitute for that element. Theoretically, each grain of the phosphide contains nearly a quarter of a grain of phosphorus. It is asserted in the journals to have been administered in doses of one or even two grains; but of the pure salt such amounts would be extremely dangerous; the commencing *dose* is one-twentieth of a grain (0.003 Gm.).

Zinc Salicylate. *Zinci Salicylas. Zinksalicylat,* G. $Zn(C_6H_4.OH.COO)_2 + 3H_2O$.—Made by boiling together molecular proportions of sodium salicylate and zinc sulphate, cooling, washing the crystals and recrystallizing from hot water. In the form of long satiny needle-like crystals, having a sweet but astringent and bitter taste. It is soluble in about 20 parts of cold water. Zinc salicylate is an astringent and antiseptic, a solution (one-fifth to one per cent.) is used in *ophthalmia* and *gonorrhea.* It is incompatible with iron compounds and with mineral acids.

Zinc Subgallate. *Zinci Subgallas.*—An odorless powder containing 44 per cent. of zinc oxide and 56 per cent. of gallic acid. Internally it is used in intestinal disorders as an antiferment in *doses* of from one-half to four grains (0.032–0.26 Gm.). It is incompatible with iron compounds and with alkaloidal salts. Externally it has been used in *skin diseases.*

Zinc Sulphite. *Zinci Sulphis.* $ZnSO_3 + 2H_2O$. —Made by precipitating a solution of zinc sulphate with sodium sulphite, collecting, washing and drying the precipitate. A white crystalline powder, soluble in about 600 parts of water.

Zincopyrin. *Phenyl-dimethyl-pyrazolone Zinc Chloride.* $(C_{11}H_{12}N_2O)_2ZnCl_2$.—It is a double salt made with one molecule of zinc chloride and two of antipyrine. It occurs as shining scales soluble in about 20 parts of water. It is used as a caustic in inoperable *cancers.*

Zirconium. Zr = 90.6.—*Zirconium dioxide* is a heavy white insoluble powder which has been used by Kaestle (*M. M. W.*, 1909) for making X-ray examinations of internal organs. According to this author it is the most opaque substance available except thorium oxide and has the advantage of being much cheaper.

Zizyphus. *Zizyphus sativa* Gaertn. (*Z. vulgaris* Lamarck.) *Jujube,* Fr. *Brustbeeren, Judendornbeeren,* G.—A shrub, or small tree, of the Fam. *Rhamnaceæ,* growing on the shores of the Mediterranean, and cultivated in Italy, Spain, and the south of France. The fruit is the part used. This consists of oval drupes, of the size of a large olive, with a thin, coriaceous, red or reddish-brown skin, a yellowish, sweet, acidulous pulp, and an oblong, pointed stone in the center. These have the name of *jujubæ.* By drying, their pulp becomes softer and sweeter, and acquires a vinous taste, evincing the commencement of fermentation. They are nutritive and demulcent, and are used in the form of decoction in *pectoral complaints. Jujube paste* consists properly of gum arabic and sugar, dissolved in a decoction of this fruit and evaporated to the proper consistence. As a demulcent it is in no respect superior to a paste made with gum arabic and sugar alone, and the preparation formerly sold in this country under the name contains in fact none of the fruit. The fruits of two other species, *Z. Lotus* Lam., growing in the north of Africa, and *Z. Jujuba* Lam., a native of the East Indies, possess properties similar to those of the *Z. sativa* and are used as food by the inhabitants of the countries where they grow. The *Zizyphus Jujuba* is stated by Bosisto (*A. J. P.*, 1886) to be one of the main sources of stick-lac, from which shellac is manufactured.

Zygadenus. *Death Comas.*—One or more species of this liliaceous genus, found in the Western United States, are highly toxic to grazing animals, notably to sheep. H. S. Goodell affirms that he has seen violent convulsions produced by the juice of *Z. venenosus* Watson. Slade (*A. J. P.*, 1905, p. 262) obtained an alkaloid from *Z. venenosus,* which resembled veratalbine. Heyl and others (*J. A. C. S.*, 1911 and 1913) obtained an alkaloid from the leaves of *Z. intermedius, zygadenine,* which resembled veratrine.

Zymoidin.—A powder said to be composed of zinc oxide, bismuth oxide, aluminum oxide, iodine, boric acid, carbolic acid, gallic acid, salicylic acid, quinine, and other ingredients. It is used as an antiseptic and dusting powder.

PART III

SECTION I

In this division are included the subjects formerly embraced in the Appendix of this work, with the addition of the official tests and various tables, and an abstract of the preparations of the National Formulary.

Reagents, Test Solutions, and Volumetric Solutions

U. S. P. Ninth Decennial Revision

The constant reference to tests in the previous pages, and the adoption of volumetric test solutions in the U. S. Pharmacopœias, and the British Pharmacopœia, necessitate the insertion of the official reagents and solutions used in the quantitative and qualitative tests. Great care should be used, in preparing these tests and selecting the reagents, to see that they come fully up to the official requirements, as the whole value of the test depends upon the purity of the reagent and the accuracy with which the solution has been made.

INTRODUCTORY

Official Substances as Reagents.—Latin official names are not used as titles in the following list, the English names being preferred. Some official substances (chemicals, chemical solutions, etc.) are sufficiently pure to be used as reagents, if they comply with the tests of purity prescribed by the Pharmacopœia. In the case of other official substances, the presence of certain impurities, though immaterial for their use as medicines, renders them unsuitable for employment as reagents. Whenever a greater degree of purity is required than is provided for by the text of the Pharmacopœia, it will be specially mentioned in the following list.

Abbreviations and Signs Used:

T.S. = Test Solution.

V.S. = Volumetric Solution.

$\frac{N}{1}$ = Normal (see under "Volumetric Solutions," page 1692).

$\frac{N}{2}$ = Half-normal; $\frac{N}{10}$ = Tenth-normal; $\frac{N}{50}$ = Fiftieth-normal; $\frac{N}{100}$ = Hundredth-normal; $\frac{N}{200}$ = Two-hundredth-normal.

$\frac{2N}{1}$ = Double-normal (sometimes written: 2N).

Keeping of Reagents.—Preserve reagents in bottles made of glass as free as possible from lead or arsenic and closed by well-ground glass stoppers or, in certain cases, rubber stoppers. Ground glass stoppers of bottles containing alkali hydroxides, ammonium sulphide, ammonia water, and other substances of alkaline reaction, which rapidly attack ground glass surfaces, are to be coated with a thin film of petrolatum.

Keep reagents which are easily affected by light, such as hydrogen sulphide T.S., ammonium sulphide T.S., chlorine water, silver nitrate T.S., etc., in bottles made of dark amber-colored glass.

NOTE.—As some of the following test solutions are in certain cases directed to be used in definite quantities, it is important that they always be prepared of the *exact strength prescribed* and measured at the standard temperature of 25° C. (77° F.).

Water, whenever required or mentioned as a solvent in the tests given in the Pharmacopœia, or in the preparation of any reagent, is always understood to be *distilled water*.

Reagents and Test Solutions

The reagents are arranged in alphabetical order and the test solutions are usually mentioned in connection with the principal chemical or other substance from which they are prepared.

Acetic Acid.—Use the official acetic acid (see page 14).

Acetic Anhydride (Acetic Acid Anhydride), $(CH_3.CO)_2O$.—A colorless, mobile, refractive liquid of pungent acetic odor, boiling at about 137° C. (278.6° F.). Specific gravity about 1.07 at 25° C. (77° F.). When poured into water it sinks at first, but gradually dissolves, forming acetic acid. Dilute 1 mil with about 50 mils of distilled water, add 5 mils of nitric acid, and mix well; the solution gives no reaction upon the addition of silver nitrate T.S. (*hydrochloric acid*). Evaporate 10 mils of acetic anhydride to dryness, completing the drying at 110° C. (230° F.); the residue weighs not more than 0.5 milligrammes (*non-volatile matter*).

Dissolve 10 mils of acetic anhydride accurately weighed in sufficient distilled water to measure 100 mils and titrate 10 mils of this with normal potassium hydroxide V.S., using phenolphthalein T.S. as indicator; not less than 19.3 mils is required to neutralize 1 Gm. of acetic anhydride. Preserve acetic anhydride in glass-stoppered vials in a cool place.

Acetone.—Use the official acetone (see page 9).

Albumen Test Solution.—Carefully separate the white of a strictly fresh hen's egg from the yolk, shake it thoroughly with 100 mils of distilled water, and filter. This solution must be freshly made when required.

Alcohol, 94.9 per cent.—Use the official alcohol (see page 108) containing not less than 94.9 per cent., by volume, of C_2H_5OH at 15.6° C. (60° F.). Alcohol of lower strength is prepared as follows:

Alcohol, 90 per cent.—Mix 51 mils of alcohol (see page 108) with 3 mils of distilled water. The specific gravity of the mixture is 0.834 at 15.6° C. (60° F.), corresponding to 90 per cent., by volume, of C_2H_5OH.

Alcohol, 80 per cent.—Mix 45.5 mils of alcohol (see page 108) with 9.5 mils of distilled water. The specific gravity of the mixture is 0.864 at 15.6° C. (60° F.), corresponding to 80 per cent., by volume, of C_2H_5OH.

Alcohol, 70 per cent.—Mix 38.6 mils of alcohol (see page 108) with 15 mils of distilled water. The specific gravity of the mixture is 0.890 at 15.6° C. (60° F.), corresponding to 70 per cent., by volume, of C_2H_5OH.

Alcohol, Dehydrated, C_2H_5OH.—Use the official dehydrated alcohol (see page 107), containing not less than 99 per cent., by volume, of C_2H_5OH.

Ammonia, Spirit of.—An alcoholic solution of ammonia (NH_3) containing 10 per cent., by weight, of the gas. It responds to the tests for purity given under ammonia water (see page 167).

Ammonia Test Solution.—Use the official ammonia water (see page 166).

Ammonia Carbonate Test Solution.—Dissolve 20 Gm. of ammonium carbonate (see page 130) in a mixture of 20 mils of ammonia water and 65 mils of distilled water, and add sufficient distilled water to measure 100 mils.

Ammonium Chloride Test Solution.—Dissolve 10 Gm. of ammonium chloride, NH_4Cl (see page 132), in sufficient distilled water to measure 100 mils. In addition to the tests prescribed for this salt under ammonium chloride (see page 133), the following must be complied with when employed in the test for lead under citric acid, tartaric acid, potassium bitartrate, or potassium and sodium tartrate. Dissolve 3 Gm. of the salt in 10 mils of distilled water acidified with 1 drop of diluted hydrochloric acid in a test tube of colorless glass having an internal diameter of 2 cm., add 10 mils of hydrogen sulphide T.S., which must be perfectly clear and colorless, and mix well. The liquid must show no discoloration when viewed downward against a white surface.

Ammonium Molybdate Test Solution.—Mix 6.5 Gm. of finely powdered molybdic acid (see page 1685) with 14 mils of distilled water and 14.5 mils of stronger ammonia water to effect solution. Cool and slowly add the solution, in small portions with agitation, to a well cooled mixture of 32 mils of nitric acid and 40 mils of distilled water. Allow the solution to stand for twenty-four hours and then filter through asbestos.

Preserve the test solution in the dark, and, if a sediment should form in it after some days, carefully decant the clear solution. This solution should be tested at frequent intervals. Add 2 mils of sodium phosphate T.S. to 5 mils of the reagent; an abundant yellow precipitate forms either at once or upon slight warming. If only a slight precipitation or yellow opalescence results, the reagent must be rejected. When employed as a reagent, ammonium molybdate T.S. is always added in large excess to the solution being tested, the latter having previously been strongly acidified with nitric acid.

Ammonium Nitrate, NH_4NO_3.—Colorless crystals, soluble in less than their own weight of water, and in about 10 parts of alcohol. This salt when used as a reagent conforms to the tests for purity given under ammonium chloride (see page 132) and in addition responds to the following tests: Ten mil portions taken separately of an aqueous solution of the salt (1 in 10), acidulated with a few drops of nitric acid, yield no turbidity on the addition of a few drops of silver nitrate T.S. (*chloride*) or a few drops of barium nitrate T.S. (*sulphate*). Dissolve 1 Gm. of ammonium nitrate in 10 mils of distilled water, add a few drops of potassium iodide T.S., 1 mil of acetic acid and a few drops of starch T.S.; no blue color is produced (*nitrite*).

Ammonium Oxalate Test Solution.—Dissolve 4 Gm. of crystallized ammonium oxalate, $(NH_4)_2C_2O_4+H_2O$, in sufficient distilled water to measure 100 mils, or dissolve 3.548 Gm. of purified oxalic acid (see page 1686) in 90 mils of distilled water, add 13 mils of ammonia water, boil to expel any excess of ammonia, and dilute with distilled water to make 100 mils.

Evaporate 50 mils of the test solution and ignite the residue, or ignite 2 Gm. of the salt; it leaves not more than 0.02 Gm. of residue (*fixed impurities*). The precipitate produced by the addition of silver nitrate T.S. or by barium chloride T.S., when added to 25 mils of the test solution, dissolves without residue upon the addition of nitric acid (*chloride and sulphate*).

Ammonium Polysulphide Test Solution.—A yellow liquid, made by dissolving a small quantity of the official precipitated sulphur (see page 1083) in colorless ammonium sulphide T.S.

Ammonium Sulphate, $(NH_4)_2SO_4$.—This salt must respond to the following tests for purity: Two Gm. yields not more than 0.002 Gm. of residue on ignition (*fixed impurities*). Five mils of an aqueous solution of the salt (1 in 10) does not respond to the Test for heavy metals (see Test No. 3). Five mils of a similar solution shows no turbidity upon the addition of nitric acid and silver nitrate T.S. (*chloride*). Another 5 mils of the solution (1 in 10) is not colored red upon the addition of 1 mil of hydrochloric acid and 1 drop of ferric chloride T.S. (*sulphocyanate*). This salt may be prepared by cautiously neutralizing ammonia water with sulphuric acid, which has been previously diluted with about two volumes of distilled water, evaporating and crystallizing. During the evaporation, the solution should be tested with litmus paper, from time to time adding more ammonia if necessary to keep the liquid alkaline.

Ammonium Sulphide Test Solution.—Saturate 3 parts of ammonia water (see page 166) with hydrogen sulphide, prepared as directed on page 1682, and add to the solution (which now contains ammonium hydrogen sulphide, NH_4HS) 2 parts of ammonia water, which converts the greater portion of the ammonium hydrogen sulphide into ammonium sulphide, $(NH_4)_2S$. Ten mils of the clear ammonium sulphide T.S., when evaporated to dryness and then gently ignited, leaves a residue weighing not more than 0.005 Gm. (*non-volatile matter*). It is not rendered turbid either by magnesium sulphate T.S. (*free ammonia*), or by calcium chloride T.S. (*ammonium carbonate*). Protect it from air and light by keeping it in small, dark amber-colored bottles, in a cool, dark place. As soon as a notable deposit of sulphur has made its appearance in the solution reject it.

Ammonium Vanadate (Ammonium Metavanadate), NH_4VO_3.—A white crystalline powder, soluble in about 100 parts of cold water and readily soluble in boiling water, forming a yellow liquid. This color is due to partial decomposition through loss of ammonia. When heated the salt assumes a yellow color which changes to brown, then reddish-brown, as the temperature rises.

Amyl Alcohol, $C_5H_{11}OH$.—A colorless, oily liquid having a penetrating characteristic odor, boiling between 128° and 132° C. (262.4° and 269.6° F.); soluble in 40 parts of water at 25° C. (77° F.); miscible with alcohol, ether, chloroform, carbon disulphide, petroleum benzin, benzene, or fixed or volatile oils. Ten mils of amyl alcohol, when evaporated to dryness on a water bath, yields not more than 0.0005 Gm. of residue.

Aniline (Phenylamine), $C_6H_5NH_2$.—When freshly distilled, aniline is a colorless, strongly refractive, oily liquid, having a peculiar, aromatic odor and a pungent, burning taste. Upon exposure to the light and air, it rapidly assumes a reddish-brown color. Specific gravity, about 1.02 at 25° C. (77° F.). Aniline distils completely between 182° and 184° C. (359.6° and 363.2° F.). It is soluble in alcohol, ether, or the fixed or volatile oils. With acids, it forms soluble crystalline salts. When added to an aqueous solution of calcium or sodium hypochlorite, a blue or purple color is produced. Preserve it in amber-colored bottles.

Aniline Sulphate, $(C_6H_5NH_2)_2H_2SO_4$.—Add gradually 10 Gm. of aniline, $C_6H_5NH_2$, to about 7 Gm. of sulphuric acid, stirring constantly. Dissolve the resulting solid mass in sufficient boiling diluted alcohol and set it aside for crystallization. Collect the crystals upon a filter, and, after draining them, recrystallize the salt from diluted alcohol. Collect the crystals on a filter and finally dry them in a desiccator. Aniline sulphate forms white crystals very soluble in water, less soluble in diluted alcohol, and slightly soluble in alcohol.

Aniline Sulphate Test Solution.—Dissolve 5 Gm. of aniline sulphate in 40 mils of distilled water, add 51 mils of diluted alcohol (see page 110) and sufficient distilled water to make 100 mils.

Arsenic Acid (Ortho-arsenic Acid), $H_3AsO_4+\frac{1}{2}H_2O$.—In white crystals or as a crystalline mass, very hygroscopic, readily soluble in water and alcohol. It fuses at about 100° C. (212° F.), becoming anhydrous at 110° C. (230° F.). At higher temperatures, it is converted into the pyro-acid and, finally, at 200° C. (392° F.) into the meta-acid. The addition of silver nitrate T.S. to an aqueous solution of arsenic acid, followed by the gradual addition of ammonia water, drop by drop, produces a red-brown precipitate which is readily soluble in a slight excess of ammonia water. With magnesia mixture T.S., arsenic acid solutions give a white crystalline precipitate. One mil of an aqueous solution of the salt (1 in 10) after neutralizing with sodium carbonate does not decolorize 1 drop of iodine T.S. (*arsenous oxide*). To 10 mils of a solution of ferrous sulphate (1 to 10) add 0.5 mil of an aqueous solution of arsenic acid (1 in 10) and float this over concentrated sulphuric acid contained in a test tube; no brown ring is formed at the zone of contact (*nitric acid*).

Arsenic Acid Test Solution, Concentrated.—For use in the assay for eucalyptol prepare this solution by dissolving 85 Gm. of crystalline arsenic acid (see above) in sufficient distilled water to make the product weigh 100 Gm. This solution has a specific gravity of about 2.173 at 25° C. (77° F.). The test solution may also be prepared by adding 56 Gm. of arsenic trioxide, in small portions, to 60 mils of nitric acid contained in a porcelain evaporating dish, stirring continuously and warming gently to assist the evolution of nitrous vapors. When all of the arsenic trioxide has been added, evaporate to a syrupy consistence, add about 25 mils of distilled water and again evaporate, and then repeat this operation once more. Finally dilute with distilled water until the solution weighs 100 Gm. This solution must comply with the tests for identity and purity given under *Arsenic Acid* (see above). If the tests indicate the presence of arsenous oxide, more nitric acid must be added and the evaporation repeated. If nitric acid is present, the solution should be repeatedly diluted and evaporated.

Arsenic Trioxide (Arsenous Oxide), As_2O_3.—For use in the Arsenic Test use arsenic trioxide which complies with the description and tests given in Part I (see page 192).

Asbestos.—The anhydrous, silky, well-matted variety (not serpentine), commercially known as "Asbestos Wool," which when moistened readily wads when rolled between the fingers. For use as a filtering medium for the "Gooch" crucible, remove the soluble matter by boiling it for one hour with diluted hydrochloric acid, and washing it with boiling water, by decantation, until free from acid. Finally transfer it to a wide-mouthed bottle containing distilled water. When desired for use, shake the mixture and pour it into a Gooch crucible which is attached to a suction pump, distributing the asbestos uniformly over the bottom in a layer sufficiently thick to retain a precipitate.

Azolitmin.—See under *Indicators* (page 1707).

Azolitmin Test Solution.—See under *Indicators* (page 1707).

Azur II (Azur Blue II, Methylene-Azur II).—A mixture of equal parts of the chlorides of methylene blue (tetramethylthionine) and methylene-azur (methylene blue sulphonate). A dark green powder, entirely soluble in water with a deep blue color, less soluble in alcohol and slightly soluble in chloroform; insoluble in ether. The addition of tannic acid T.S. to an aqueous solution of azur II (1 in 1000) produces a blue precipitate. The addition of a few drops of hydrochloric acid to a mixture of 5 mils of an aqueous solution of this dye (1 in 1000) and 0.5 Gm. of zinc dust causes decolorization. When the decolorized mixture is filtered, and solution of hydrogen dioxide is added, the deep blue color is restored (reduction to leuco base and reoxidation). The addition of either hydrochloric acid or ammonia water to an aqueous solution of azur II (1 in 1000) produces no change. The addition of sodium hydroxide T.S. to an aqueous solution of azur II (1 in 1000) produces a violet coloration; upon heating the solution a violet precipitate is formed. The addition of potassium iodide T.S. to an aqueous solution of the dye (1 in 1000) produces a violet precipitate; the addition of potassium dichromate T.S. produces a red-violet precipitate. Azur II dissolves in concentrated sulphuric acid with a bright green color [distinction from *methylene violet* (dimethylthionolin)]; upon cautiously diluting with distilled water the solution assumes a blue color, remaining clear. Acidulate an aqueous solution of azur II (1 in 1000) with a few drops of hydrochloric acid, then shake it with ether, remove the ethereal layer, and shake it with a diluted solution of sodium hydroxide T.S.; the latter remains uncolored (distinction from *azur II-eosin*).

Azur II-Eosin.—A mixture of methylene blue eosin (methylene blue eosinate) and methylene-azur-

eosin (methylene blue sulphone-eosinate). A dark green powder only very slightly soluble in water, more readily soluble in alcohol or glycerin. A warm saturated aqueous solution of azur II-eosin (about 1 in 2000) possesses a blue color with intense shading into violet. Highly dilute solutions possess a slight, greenish opalescence. Its solutions in alcohol or glycerin possess the same color with a strong yellowish-green fluorescence. A saturated aqueous solution of azur II-eosin is precipitated upon the addition of tannic acid T.S. The addition of zinc dust and ammonia water to an aqueous solution of this dye causes decolorization. When filtered, the colorless filtrate, upon standing in the air, quickly assumes a blue color (reduction to a leuco base and reoxidation to original color). A hot, saturated and filtered, aqueous solution of azur II-eosin assumes a pale blue color upon the addition of hydrochloric acid, and the dye separates in blue flocculles. If this acid solution is agitated with ether and the ethereal layer removed and shaken with diluted sodium hydroxide T.S., the latter assumes an eosin color (distinction from *azur II*). The addition of sodium hydroxide T.S. to a saturated aqueous solution of azur II-eosin intensifies its violet color. Azur II-eosin dissolves in concentrated sulphuric acid with a deep green color which, upon dilution with water, changes to a blue, a portion of the dye (eosin) separating in flocculles (distinction from *azur II*).

Barium Chloride, $BaCl_2+H_2O$.—Transparent crystals, easily soluble in water, almost insoluble in alcohol or concentrated hydrochloric acid. An aqueous solution of the salt (1 in 20) is neutral and does not respond to the Test for heavy metals (see Test No. 3). Dissolve 2 Gm. of barium chloride in 100 mils of distilled water, add 2 mils of hydrochloric acid, heat to boiling, then add a slight excess (about 10 mils) of diluted sulphuric acid, set it aside for twelve hours, and filter. The clear filtrate, on evaporating and igniting, yields a residue weighing not more than 0.002 Gm. (*other fixed bases*). Shake 1 Gm. of the finely powdered salt with 20 mils of dehydrated alcohol during five minutes and filter; the filtrate on evaporation and ignition yields not more than 0.002 Gm. of residue (*strontium and calcium*).

Barium Chloride Test Solution.—Dissolve 10 Gm. of barium chloride in sufficient distilled water to measure 100 mils.

Barium Hydroxide, $Ba(OH)_2+8H_2O$.—White crystals, soluble in about 20 parts of cold water and 3 parts of boiling water. The salt readily absorbs carbon dioxide from the air, forming an insoluble carbonate, hence aqueous solutions are more or less turbid. A solution of 1 Gm. of barium hydroxide in 50 mils of distilled water and 5 mils of nitric acid shows no opalescence upon the addition of silver nitrate T.S. (*chloride*). Dissolve 2 Gm. of the salt in 100 mils of distilled water, add 5 mils of hydrochloric acid, heat to boiling, then add a slight excess of diluted sulphuric acid, set it aside for twelve hours, and filter; the clear filtrate, on evaporating and igniting, yields a residue weighing not over 0.003 Gm. (*other fixed bases*). The solution of 1 Gm. of barium hydroxide in 20 mils of distilled water rendered acid with hydrochloric acid, does not respond to the Test for heavy metals (see Test No. 3). One Gm. of barium hydroxide dissolved in 100 mils of distilled water requires not less than 6.3 mils of normal hydrochloric acid V.S. for neutralization, using methyl orange T.S. or methyl red T.S. as indicator. Each mil of normal hydrochloric acid V.S. corresponds to 0.157755 Gm. of barium hydroxide [$Ba(OH)_2+8H_2O$].

Barium Hydroxide Test Solution.—A saturated solution of barium hydroxide (see above) in recently boiled distilled water. This solution rapidly absorbs carbon dioxide from the air. Prepare a fresh solution when required for use.

Barium Nitrate, $Ba(NO_3)_2$.—Colorless crystals, soluble in 20 parts of cold water and 2.8 parts of boiling water; its solution is neutral to litmus. The addition of silver nitrate T.S. to an aqueous solution of the salt (1 in 20) produces no change (*chloride*). Barium nitrate meets the requirements of the tests for "other fixed bases" and "heavy metals" given under *Barium Chloride* (see above).

Barium Nitrate Test Solution.—Dissolve 5 Gm. of barium nitrate in sufficient distilled water to measure 100 mils.

Beef Extract (Meat Extract).—Use extract of beef complying with the tests of the U. S. Department of Agriculture, preferably the kind known as "Liebig's."

Benzene (Benzol or Benzole).—Benzene, C_6H_6, is a colorless, transparent, inflammable liquid of a peculiar, aromatic odor; specific gravity about 0.876 at 25° C. (77° F.); congealing at about 5.2° C. (41.4° F.); boiling between 79° and 80.4° C. (174.2° and 176.7° F.). It is insoluble in water, but soluble in 4 parts of alcohol and also in ether. When equal volumes of benzene and concentrated sulphuric acid are shaken together, the latter is not colored. Shake 2 mils of benzene with 0.5 mil of sulphuric acid and 1 drop of fuming nitric acid; no green or blue tint is produced (*thiophene*).

Benzidine (Paradiaminodiphenyl), $(C_6H_4)_2(NH_2)_2$.—A white or slightly reddish crystalline powder. It is very slowly soluble in cold water, more readily in boiling water; soluble in alcohol and in ether. It melts at about 128° C. (262.4° F.). On adding a few drops of barium chloride T.S. to a solution of 1 Gm. of benzidine in 50 mils of distilled water acidulated with 5 mils of hydrochloric acid, no turbidity is produced (*sulphate*). One Gm. of benzidine upon ignition leaves no weighable residue.

Benzin (Petroleum Benzin).—Use the official purified petroleum benzin.

Beta-iminazolyl-ethylamine Hydrochloride.—Used in standardizing solution of the pituitary body (see page 646).

Blood Serum.—The serum filtered from the clotted blood of the horse or ox.

Bromine, Br.—Preserve it in a glass-stoppered bottle in a cool place, the bottle being enclosed in a larger vessel with the space between filled with some substance (as calcium hydroxide) capable of absorbing and combining with any vapors which might be given off. A heavy, dark brownish-red, mobile liquid, evolving, even at ordinary temperatures, reddish fumes, highly irritating to the eyes and lungs, and having a peculiar, suffocating odor; resembling that of chlorine. Specific gravity about 3.1 at 25° C. (77° F.). Boiling point, about 63° C. (145.4° F.). Bromine is soluble in 90 times its volume of water at 25° C. (77° F.); freely soluble in alcohol or ether (with gradual decomposition of these solvents); also soluble in chloroform, carbon disulphide, or carbon tetrachloride with a deep reddish-yellow color. On exposure to air or to heat, it is volatilized. Bromine destroys the color of solutions of litmus or indigo, and imparts a yellow color to starch T.S. Add 5 mils of bromine to an excess of potassium hydroxide T.S.; it combines to form a permanently clear liquid, without the separation of oily drops (*organic bromine compounds*). Shake 10 mils of a saturated aqueous solution of bromine with a slight excess of reduced iron until it becomes nearly colorless; the filtered liquid, on the addition of 5 drops of ferric chloride T.S. and of 5 drops of starch T.S., does not assume a blue color (*iodine*).

Bromine Test Solution (Bromine Water).—A saturated aqueous solution of bromine prepared by adding 3 mils of bromine to 100 mils of cold distilled water contained in a glass-stoppered bottle, the stopper of which should be lubricated with petrolatum. Keep this reagent in a cool place, protected from light, and shake it well, allowing the excess of bromine to settle, before using.

Cadmium and Potassium Iodide.—A mixture of equal weights of cadmium iodide and potassium iodide (see page 902) may be employed. A white powder readily soluble in water or alcohol. Upon keeping it acquires a yellowish color. Dissolve 1 Gm. of the powder in 20 mils of distilled water, add 5 mils of potassium hydroxide T.S., and filter the solution; the filtrate yields no precipitate with hydrogen sulphide T.S. either before or after acidulating with hydrochloric acid (*foreign metals*). An aqueous solution of the salt (1 in 20) prepared with distilled water, which has been previously boiled and cooled, gives no blue color upon the addition of starch T.S. (*free iodine*).

Cadmium Chloride, $CdCl_2+2H_2O$.—Small white crystals which effloresce in dry air and are soluble in about 0.7 part of cold or hot water. An aqueous solution of the salt gives a yellow precipitate with ammonium sulphide T.S. which is insoluble in an excess of the reagent.

Cadmium Chloride Test Solution.—Dissolve 10 parts of cadmium chloride in sufficient distilled water to make 100 parts.

Cadmium Iodide, CdI_2.—Colorless to yellowish, glossy scales, soluble in 1.1 parts of cold water and in 0.75 part of boiling water, readily soluble in alcohol. Solutions of this salt, upon the addition of alkali hydroxides, yield a white precipitate of cadmium hydroxide insoluble in an excess of the reagent; the precipitate produced by the addition of ammonia water is soluble in an excess of the reagent. Hydrogen sulphide T.S. or ammonium sulphide T.S. added to an aqueous solution of the salt yields yellow cadmium sulphide which is insoluble in an excess of the latter reagent. Add 10 mils of potassium hydroxide T.S. to a solution of 1 Gm. of cadmium iodide in 20 mils of distilled water, and filter; the filtrate yields no precipitate with hydrogen sulphide T.S. either before or after acidulating with hydrochloric acid (*foreign metals*).

Calcium Chloride Test Solution.—Dissolve 10 Gm. of calcium chloride (see page 254) in sufficient distilled water to measure 100 mils.

Calcium Hydroxide Test Solution (Lime Water), a nearly saturated, aqueous solution of calcium hydroxide, $Ca(OH)_2$.—Use lime water (see page 630).

Calcium Sulphate Test Solution.—Introduce pulverized transparent crystals of native gypsum (selenite), ($CaSO_4+2H_2O$), into a bottle nearly filled with distilled water, agitate it at intervals for twelve hours, and decant the clear, saturated solution when required. One part of gypsum requires about 400 parts of water for solution at 25° C. (77° F.). The test solution may also be made by shaking together 1 Gm. of calcium carbonate and 200 mils of distilled water, containing 5 mils of diluted sulphuric acid. When the acid is completely neutralized filter the mixture.

Canada Turpentine.—A liquid oleoresin obtained from *Abies balsamea* (Linné) Miller (Fam. *Coniferæ*). Viscid, pale yellowish or greenish-yellow, transparent; odor agreeable, taste terebinthinate, bitter, and slightly acrid; it is completely soluble in ether, chloroform, or benzene. When exposed to the air, Canada turpentine gradually dries and forms a transparent varnish; it solidifies on being mixed with 20 per cent. of its weight of magnesium oxide previously moistened with water.

Carbon Disulphide, CS_2 (Carbon Bisulphide).—Preserve in partially filled, well-stoppered bottles, or in tin cans, in a cool place, remote from flame or fire. A clear, colorless, highly-refractive liquid, very volatile, having a strong, characteristic but not fetid odor, and a sharp, aromatic taste. Specific gravity between 1.256 and 1.257 at 25° C. (77° F.). Soluble in about 530 parts of water at 25° C. (77° F.); very soluble in alcohol, ether, chloroform, or fixed or volatile oils. Carbon disulphide vaporizes rapidly at the ordinary temperature, is highly inflammable, boils between 46° and 49° C. (114.8° and 120.2° F.), and when ignited, burns with a bluish-white flame, producing carbon dioxide and sulphur dioxide. It does not affect the color of blue litmus paper moistened with water (*sulphur dioxide*). Twenty mils when allowed to evaporate spontaneously in a glass dish and finally on a water bath leaves not more than 0.001 Gm. of residue (*dissolved sulphur*). No discoloration is produced in 10 mils of lead acetate T.S. after agitating with 25 mils of carbon disulphide, when viewed from above in a test tube of about 2 cm. in diameter (*hydrogen sulphide*).

Carbon Tetrachloride, CCl_4.—A colorless, heavy liquid, of characteristic odor; non-inflammable; specific gravity about 1.58 at 25° C. (77° F.), boiling point between 76° and 77° C. (168.8° and 170.6° F.). It is immiscible with water, but miscible with dehydrated alcohol, ether, or fixed or volatile oils. Shake 10 mils with 20 mils of distilled water and allow the liquids to separate completely; the water remains neutral to litmus, and becomes not more than slightly opalescent on the addition of silver nitrate T.S. (*chloride*), and is not colored by potassium iodide T.S. (*chlorine*). Twenty-five mils when evaporated on a water bath leaves not more than 0.0005 Gm. of residue (*non-volatile matter*). To 10 mils of a solution of potassium hydroxide in dehydrated alcohol (1 in 10), add 10 mils of carbon tetrachloride; after standing for one hour, acidify with acetic acid and add 1 mil of copper sulphate T.S.; no yellow precipitate appears within two hours (*carbon disulphide*).

Carmine.—A lake color obtained from cochineal by the precipitation of its aqueous infusion with inorganic salts and albumen. Bright red, light and friable lumps, insoluble in cold water and acids, partially soluble in hot water, soluble in ammonia water with a dark red color. When dried at 100° C. (212° F.), 1 Gm. of carmine loses not more than 0.25 Gm. in weight; the residue ignited cautiously in a porcelain crucible, leaves not more than 0.12 Gm. of ash. During the ignition no odor like that of phenol or bromine is perceptible (*aniline colors*). Excepting for a few floccules, 0.15 Gm. of carmine dissolves completely in a mixture of 5 mils of ammonia water and 20 mils of distilled water.

Chlorine Test Solution (Chlorine Water).—Place 10 Gm. of manganese dioxide (see page 680) in a flask connected by a suitable tube with a small wash bottle containing 50 mils of water, and connect this with a bottle having a capacity of 1000 mils and containing 400 mils of distilled water which has previously been boiled and allowed to cool. Add to the dioxide in the generating flask 25 mils of hydrochloric acid, previously diluted with 25 mils of water, and apply a gentle heat by means of a sand bath. Conduct the generated chlorine through the water contained in the wash bottle into the bottle containing the distilled water, which should be loosely stopped with cotton and kept, during the operation, at a temperature of

about 10° C. (50° F.). When the air has been entirely displaced by the gas, disconnect the bottle from the apparatus, and, having inserted the stopper, shake the bottle, loosening the stopper from time to time, until the gas ceases to be absorbed. If necessary, reconnect the bottle with the apparatus, and continue passing the gas and agitating, until the distilled water is saturated. Finally, pour the chlorine water into small, dark amber-colored, glass-stoppered bottles, which should be completely filled, and preserve them in a dark and cool place.

Chlorine Water, even when kept from light and air, is apt to deteriorate. When it is required of full strength, it should be freshly prepared.

Chloroform, $CHCl_3$.—Use chloroform (see page 323).

Cobaltous Chloride, $CoCl_2+6H_2O$.—Rose-colored, monoclinic crystals, nonhygroscopic, soluble in water or alcohol. Dissolve 2 Gm. of the salt in about 100 mils of distilled water, completely precipitate the cobalt by the addition of an excess of ammonia water followed by ammonium sulphide T.S., and filter; the filtrate, after evaporation and ignition, leaves not more than 0.008 Gm. of residue (*alkali salts*). Add 3 Gm. of sodium cyanide to a solution of 1 Gm. of cobaltous chloride, in about 20 mils of distilled water, boil until the solution acquires a yellow color and filter it; on the addition of about 1 mil of bromine followed by sufficient potassium hydroxide T.S. to render the solution strongly alkaline no brown color develops (*nickel*). No coloration is produced in a solution of 2 Gm. of the salt in 100 mils of distilled water, to which 2 mils of nitric acid has been added, upon the addition of hydrogen sulphide T.S. (*lead and copper*).

Cobaltous Chloride Test Solution.—Dissolve 2 Gm. of cobaltous chloride with the aid of 1 mil of hydrochloric acid in sufficient distilled water to measure 100 mils.

Cochineal Test Solution.—See under *Indicators* (page 1707).

Congo Red.—See under *Indicators* (page 1707).

Congo Red Test Solution.—See under *Indicators* (page 1707).

Copper, Metallic, Cu.—In the form of wire, foil, or turnings.

Cupric Acetate, $Cu(C_2H_3O_2)_2+H_2O$.—Bluish-green crystals, having an acetous odor, soluble in water or alcohol. An aqueous solution of the salt (1 in 20), mixed with a few drops of hydrochloric acid, is not rendered more than slightly turbid at once, upon the addition of a few drops of barium chloride T.S. (*sulphate*). In other respects it meets the tests for purity directed under *Cupri Sulphas* (see page 393).

Cupric Acetate Test Solution.—Dissolve 1 part of cupric acetate in sufficient distilled water to make 1000 parts. Should the solution become cloudy, add acetic acid, drop by drop, until it becomes clear.

Cupric Ammonium Sulphate Test Solution.—A solution of cupri-tetrammonium sulphate, $Cu(NH_3)_4SO_4+H_2O$. To copper sulphate T.S. add ammonia water, drop by drop, until the precipitate at first formed is nearly, but not completely, redissolved, then filter. This solution should be freshly made when required.

Cupric Sulphate Test Solution.—Dissolve 10 Gm. of copper sulphate (see page 393) in sufficient distilled water to measure 100 mils.

Cupric Tartrate Test Solution.—See Volumetric Solutions (page 1694).

Curare.—Curare is an impure vegetable extract prepared by the Indians of South America and used by them as an arrow poison. Its composition is not entirely known, and different specimens of curare vary, depending upon the special variety of plant used in its manufacture. The most important source of curare is the bark of several varieties of *Strychnos*, the species most commonly employed being *S. Castelnæi*, Wedd., *S. Toxifera, or S. Crevauxii.* In addition to the extract of these barks other substances are added to impart consistence, to mislead, or perhaps from superstitious considerations. Commercial curare is a brownish or black, shining resinoid mass, possessing a very bitter taste. About 75 per cent. is soluble in cold water and it is almost completely soluble in diluted alcohol.

Dimethylaminoazobenzene (Butter Yellow), $C_6H_5N : N.C_6H_4N(CH_3)_2$.—It forms yellow plates melting between 115° and 117° C. (239° and 242.6° F.). It is insoluble in water, soluble in alcohol; soluble in hydrochloric acid with a red color from which solution sodium hydroxide T.S. in excess precipitates the orange-yellow base. The solution of this dye in sulphuric acid is yellow and changes to red on dilution with water.

Diphenylamine, $(C_6H_5)_2NH$.—In the form of grayish-white or colorless crystals, of a peculiar, aromatic odor, melting between 53° and 54° C. (127.4° and 129.2° F.); slightly soluble in water, more soluble in acids. It is used either in the dry state, or in solution in sulphuric acid, as a test for nitric acid (in sulphuric acid, water, etc.), or for chlorine (in hydrochloric acid). To test a solution for the presence of nitric acid, a small portion of it is carefully poured down the side of a test tube, slightly inclined and containing a few mils of diphenylamine T.S. so as to form a layer over the latter. The presence of nitric acid is shown by a deep blue color at the zone of contact. A similar reaction is also produced by the presence of hypochlorites, chlorates, chromium trioxide, ferric salts, and similar oxidizing agents.

Diphenylamine Test Solution.—Dissolve 0.5 Gm. of diphenylamine in 100 mils of concentrated sulphuric acid (see page 1692) diluted with 20 mils of distilled water. The solution should be colorless.

Eosin A (Yellowish Eosin), $O[C_6H(Br_2O)_2Na]C.C_6H_4COONa$.—The sodium salt of tetra-brom-fluorescein. Fine red crystals of bluish, glossy luster, or a brownish-red powder; readily soluble in water, less soluble in alcohol and insoluble in ether. A concentrated aqueous solution of eosin A has a deep brownish-red color while a dilute solution (1 in 500) is yellowish-red with a greenish fluorescence. The alcoholic solutions show a yellowish-green fluorescence. The addition of tannic acid T.S. to an aqueous solution of eosin A (1 in 500) produces no change. When about 0.5 Gm. of zinc dust, followed by 5 mils of ammonia water, is added to 5 mils of an aqueous solution of eosin A (1 in 500) and the mixture agitated, rapid decolorization takes place. When this mixture is filtered, the addition of solution of hydrogen dioxide to the filtrate restores the pink color of the solution. The addition of hydrochloric acid to an aqueous solution (1 in 500) causes an orange precipitate which, upon agitating with ether, yields a yellow solution. This solution is decolorized upon agitating it with a dilute solution of an alkali. The addition of sodium hydroxide T.S. intensifies the color of an aqueous solution of eosin A (1 in 500). Eosin A dissolves in concentrated sulphuric acid (see page 1692) with a yellow color and, when this solution is cautiously diluted with distilled water, a yellowish-red precipitate is produced.

Ether.—Use ether (see page 96). It should be neutral to moistened litmus paper.

Ether, Dehydrated, $(C_2H_5)_2O$.—Specific gravity not greater than 0.7115 at 25° C. (77° F.), it distils between 34° and 36° C. (93.2° and 96.8° F.). Add a very small quantity of powdered rosaniline acetate (see page 1688), dried at 100° C. (212° F.), to 10 mils of dehydrated ether, contained in a dry glass cylinder, stopper and shake it. No coloration results (*water or alcohol*). Add some dry tannic acid to 10 mils of dehydrated ether, contained in a dry glass cylinder, stopper and shake it; the tannin does not agglutinate or form a syrupy deposit (*water or alcohol*). Twenty mils of dehydrated ether, when permitted to evaporate spontaneously, leaves no perceptible residue, and upon rinsing the vessel with distilled water, the latter does not distinctly affect litmus paper. If the ether shows the presence of traces of moisture it should be shaken with pieces of anhydrous calcium chloride.

Ethyl Acetate (Acetic Ether), $CH_3.COOC_2H_5$.—A transparent, colorless liquid, of fragrant, acetous odor; inflammable; soluble in about 10 parts of water at 25° C. (77° F.); miscible in all proportions with alcohol, ether, or volatile oils. Specific gravity: 0.893 to 0.898 at 25° C. (77° F.); boiling point from 72° to 77° C. (161.6° to 170.6° F.). On evaporating 10 mils of ethyl acetate on a water bath no weighable residue remains (*non-volatile matter*). Ethyl acetate does not immediately redden blue litmus paper. Evaporate a portion of ethyl acetate spontaneously from clean, odorless blotting paper; the final odor, after that of the ester ceases to be noticeable, is not that of foreign esters (*butylic or amylic ester*). Agitate 25 mils of ethyl acetate with 25 mils of a saturated aqueous solution of calcium chloride and permit it to stand for complete separation; the volume of the latter does not increase more than 0.5 mil (*alcohol or water*). Mix 20 mils of ethyl acetate with a solution of 20 Gm. of sodium hydroxide in 50 mils of distilled water, allow the mixture to stand, agitating occasionally, or heat it gently under a reflux condenser, until a homogeneous liquid results, and then distil about 25 mils. This distillate complies with the test for absence of methyl alcohol under *Alcohol*. When 5 mils of ethyl acetate is poured over 5 mils of sulphuric acid, no coloration is produced at the zone of contact of the two layers (*amyl alcohol or other carbonizable impurities*).

Ferric Ammonium Sulphate, $FeNH_4(SO_4)_2+12H_2O$.—Pale violet, octahedral crystals, without odor, and having an acid, styptic taste; efflorescent on exposure to the air. Soluble in 2.7 parts of water at 25° C. (77° F.) and in 0.8 part of boiling water; insoluble in alcohol. The addition of 0.5 mil of nitric acid to 10 mils of a solution of the salt (1 in 20); followed by a few drops of silver nitrate T.S., produces no turbidity (*chloride*). The addition of a few drops of a freshly prepared solution of potassium ferricyanide T.S. to a solution of the salt (1 in 20) does not produce a blue or green color (*ferrous salt*).

Ferric Ammonium Sulphate Test Solution.—Dissolve 10 Gm. of ferric ammonium sulphate in sufficient distilled water to measure 100 mils.

Ferric Chloride Test Solution.—Dissolve 10 Gm. of ferric chloride (see page 464) in sufficient distilled water to measure 100 mils.

Ferrous Sulphate Test Solution.—Dissolve a clear crystal of ferrous sulphate (see page 472) in about 10 parts of distilled water which has been previously boiled to expel air. This solution is to be freshly prepared immediately before use.

Ferrous Sulphate (Acid) Test Solution.—Dissolve 7.5 Gm. of clear crystals of ferrous sulphate (see page 472) in 90 mils of distilled water which has been previously boiled to expel air, and then add sufficient sulphuric acid (see page 64) to measure 100 mils. This solution is to be freshly prepared immediately before use.

Ferrous Sulphide, FeS.—A heavy solid, in the form of black or brownish-black irregular masses, or cast into sticks, soluble in diluted sulphuric or diluted hydrochloric acid, with copious evolution of hydrogen sulphide.

Filter Paper, Quantitative.—For the Mercuric Bromide Test Paper of the Arsenic Test use Schleicher and Schüll's No. 589 (Blue Ribbon), or Swedish O. filter paper or other makes of like surface, quality and ash (see Arsenic Test, page 1709).

Fluorescein (Resorcinolphthalein).—A derivative [$C_{20}H_{12}O_5$ or $O(C_6H_3OH)_2C.C_6H_4COO$] of resorcinol obtained by the condensation of resorcinol and phthalic anhydride. Fluorescein occurs as a yellowish-red to dark-red powder; odorless and tasteless. It is very slightly soluble in water or ether, soluble in alcohol. Fluorescein dissolves in solutions of alkali hydroxides or carbonates, forming a liquid which appears red when observed in transmitted light and fluorescent bright-green in reflected light. An alkaline solution of fluorescein, even when highly diluted, shows a greenish-yellow fluorescence, which is discharged by the addition of a slight excess of acid. Incinerate 1 Gm. of fluorescein; the ash does not exceed 0.0025 Gm. Heat about 1 Gm. of fluorescein at a temperature below a red heat until it is completely carbonized, then boil the powdered residue with 10 mils of diluted hydrochloric acid for five minutes, filter and wash the residue with 10 mils of distilled water. The combined filtrate, when boiled with a few drops of nitric acid, and supersaturated with ammonia and filtered, if necessary, remains clear upon the addition of an equal volume of hydrogen sulphide T.S. (*zinc*). Shake about 1 Gm. of fluorescein with 20 mils of distilled water and filter; one drop of tenth-normal sodium hydroxide V.S. imparts to 10 mils of the filtrate a bright green fluorescence. The addition of a drop of ferric chloride T.S. to the remaining portion of the filtrate does not produce a bluish coloration (*resorcinol and various other phenolic compounds*).

Fuchsin (Basic Fuchsin, Magenta, Rubin, Rosaniline).—The hydrochloride or acetate of rosaniline (triamido-diphenyl-tolyl-carbinol) frequently with the same salts of para-rosaniline (triamido-triphenyl-carbinol). In well-developed crystals or irregular crystalline fragments of a glossy, greenish-bronze luster. Soluble in water, alcohol, or amyl alcohol. An aqueous solution (1 in 500), upon the addition of tannic acid T.S., yields a red precipitate. The addition of about 0.5 Gm. of zinc dust (see page 1692), and 10 mils of ammonia water to 10 mils of an aqueous solution of fuchsin (1 in 500) produces decolorization when the mixture is well shaken. Place a few drops of this decolorized solution on filter paper, and then add near by a few drops of hydrochloric acid; the zone where the two neutralizing fluids meet assumes a red color. Sulphurous acid (see page 1692), when added slowly, with agitation, to an aqueous solution of fuchsin (1 in 500) causes decolorization. The original color is restored upon the subsequent addition of a solution of formaldehyde. Upon slowly adding hydrochloric acid, to an aqueous solution of fuchsin (1 in 500), the red color gradually changes to a brownish-red which subsequently changes to a yellow when the reagent is in

excess. The addition of sodium hydroxide T.S. to an aqueous solution of fuchsin (1 in 500) precipitates the red colored free base. Finely pulverized fuchsin dissolves in concentrated sulphuric acid (see page 1692) with a yellow to yellowish-brown color, which solution, upon the cautious addition of distilled water, becomes yellow to colorless.

Fuchsin, Acid (Acid Magenta, Acid Rubin, Fuchsin S).—Chiefly the acid sodium salt of fuchsin di- and tri-sulphonic acids. Acid fuchsin occurs as metallic, greenish, glistening granules or as a greenish-brown crystalline powder; soluble in water, forming a cherry-red solution, very slightly soluble in alcohol; insoluble in ether. The addition of tannic acid T.S. to an aqueous solution of acid fuchsin (1 in 500) produces no precipitation (*acid color*). The addition of about 0.5 Gm. of zinc dust and 5 mils of ammonia water to 10 mils of an aqueous solution of acid fuchsin (1 in 500) produces decolorization when the mixture is well shaken. When this mixture is filtered, the addition of hydrochloric acid to the colorless filtrate restores its original red color. This solution, when agitated with ether, imparts no color to the latter (*phthaleins*). The addition of sodium hydroxide T.S. to an aqueous solution of the salt (1 in 500) almost decolorizes the solution. The addition of hydrochloric acid to an aqueous solution (1 in 500) produces no change. It dissolves in concentrated sulphuric acid with a yellow to brownish-red color and this solution, upon the cautious addition of distilled water, changes to its original fuchsin-red color.

Fuchsin-Sulphurous Acid Test Solution.—To a solution of 0.5 Gm. of fuchsin and 9 Gm. of sodium bisulphite (see page 1689) in 500 mils of distilled water, add 10 mils of hydrochloric acid. The quantity of sulphurous acid present should be about 5 Gm. Preserve the solution in well-stoppered bottles protected from light.

Gelatin Test Solution.—Dissolve 1 Gm. of gelatin (see page 509) in 50 mils of distilled water, with the aid of a gentle heat, and filter if necessary. This solution is to be freshly made when wanted for use.

Glass Wool (Spun Glass).—Fine threads of spun glass. Two Gm. of glass wool when digested on a bath of boiling water for one-half hour with 100 mils of diluted hydrochloric acid, the mixture filtered and the filtrate evaporated to dryness and then dried at 110° C. (230° F.), leaves not more than 0.01 Gm. of residue (*soluble matter*). Boil 1 Gm. of glass wool for a few minutes with a mixture of 25 mils each of diluted nitric acid and distilled water; filter, evaporate the filtrate to dryness, and treat the residue with 10 mils of distilled water and again filter it; the filtrate is not affected by the addition of hydrogen sulphide T.S. (*lead*).

Glucose, Dry (Dextrose, d-glucose), $C_6H_{12}O_6$.—A white, anhydrous powder which complies with the tests for identity and purity given under "*Glucosum*."

Gold Chloride (Chlorauric Acid), $AuCl_3HCl+4H_2O$.—Yellow, very hygroscopic crystals which contain about 48 per cent. of metallic gold, when assayed by moistening a weighed portion of the crystals with a slight excess of ammonium oxalate T.S., evaporating to dryness, igniting and weighing the residue. The metallic gold thus obtained does not give a positive reaction upon heating with diluted hydrochloric acid, filtering and testing the solution with either hydrogen sulphide T.S., dry glucose, or ammonium sulphide T.S.

Gold Chloride Test Solution.—Dissolve 1 Gm. of gold chloride in 30 mils of distilled water.

Gold Chloride Test Solution, Diluted.—This solution is used as a standard for the assay of Dried Suprarenals (see page 1093), and must contain 0.1 Gm. of metallic gold in each 100 mils. Accurately measure 10 mils of gold chloride test solution (see above) into a weighed porcelain crucible, add about 1 Gm. of ammonium oxalate T.S. and evaporate it to dryness; then cautiously ignite the residue until no further loss in weight occurs, and weigh. Calculate the exact amount of metallic gold present in the solution which has been assayed and then dilute the remainder with a sufficient quantity of distilled water to make each 100 mils contain 0.1 Gm. of metallic gold.

Hematein, $C_{16}H_{12}O_6$.—A product of the oxidation of hematoxylin, occurring in reddish-brown plates of a greenish metallic luster; very slightly soluble in cold water, alcohol or ether, insoluble in chloroform. It is soluble in ammonia water with a brownish-violet color and in diluted solutions of the caustic alkalies with a bright red color.

Hematoxylin and Hematoxylin Test Solution.—See under *Indicators* (page 1707).

Hydrated Chloral Test Solution.—A concentrated aqueous solution prepared by dissolving 3 parts of hydrated chloral (see page 319) in 2 parts of distilled water.

Hydrochloric Acid, Concentrated, for Tests, HCl.—An acid of specific gravity between 1.170 and 1.184 at 25° C. (77° F.) (35 to 38 per cent.), which must respond to the following tests of purity: Evaporate 100 mils of the acid to about 5 mils, dilute it with 10 mils of distilled water, and add a few drops of barium chloride T.S.; no precipitate occurs within twelve hours (*sulphuric acid*). Evaporate 50 mils of the acid to dryness on a water bath; not more than 0.002 Gm. of non-volatile residue remains (*non-volatile solids*). Add 5 mils of the concentrated acid, diluted with 50 mils of distilled water, to a solution of 1 drop of tenth-normal iodine V.S. in 50 mils of distilled water to which a few drops of starch T.S. have been added; no decolorization occurs (*sulphurous acid*). Dilute 10 mils of the acid with about 100 mils of warm distilled water (at about 50° C. (122° F.)) and thoroughly saturate it with hydrogen sulphide; no dark coloration or precipitate forms either before or after neutralizing with ammonia water and adding a few drops of ammonium sulphide T.S. (*heavy metals*). Two mils of the acid, diluted with 10 mils of distilled water, when subjected to the Arsenic Test (No. 1) produces a stain not greater than that produced by the zinc.

Hydrogen Sulphide, H_2S.—A gas generated by treating ferrous sulphide (see page 1681) with diluted sulphuric acid, and washing the gas as directed below under the Test Solution.

Hydrogen Sulphide Test Solution (Hydrosulphuric Acid).—A saturated, aqueous solution of hydrogen sulphide. To prepare about 1000 mils of the solution, treat 20 Gm. of ferrous sulphide in a suitable apparatus with a mixture of 20 mils of sulphuric acid (see page 64) and 250 mils of distilled water, pass the gas through a drying tube filled with granulated calcium chloride, then from this through a tube of about 8 millimeters diameter and 40 centimeters in length, which contains about 5 Gm. of coarsely pulverized iodine mixed with glass wool (see above), and finally through a wash bottle which contains a small quantity of potassium iodide T.S. The gas thus purified is conducted nearly to the bottom of a bottle of the capacity of about 1500 mils containing 1000 mils of cold distilled water. Shake the bottle occasionally to facilitate

the solution of the gas. When the gas is no longer absorbed, transfer the solution to small, dark amber-colored bottles, fill nearly to the top; pass a stream of purified hydrogen sulphide for a few minutes through each, and then at once stopper them tightly, and preserve them afterwards in a cool and dark place. Do not use this solution unless it retains a strong odor of hydrogen sulphide, and, when added to an equal volume of ferric chloride T.S. produces at once a copious precipitate of sulphur.

Indicators.—See special list, page 1707.

Indigo Carmine Test Solution.—Dissolve 1 Gm. of sodium indigotindisulphonate (see page 1031) in 150 mils of distilled water.

Iodeosin and Iodeosin Test Solution.—See under *Indicators* (page 1708).

Iodine, Purified.—Heat powdered iodine (see page 588) in a porcelain dish placed on a water bath for twenty minutes, and stir it constantly with a glass rod, so that adhering moisture, cyanogen iodide, and most of the iodine bromide and iodine chloride, if present, may be vaporized, then transfer the iodine to a porcelain or other non-metallic mortar, and triturate it with about 5 per cent. of its weight of dry potassium iodide, so as to decompose any remaining iodine bromide and iodine chloride. Then return the mixture to the dish, cover it with a glass funnel, and heat the dish carefully on a sand bath. Detach the sublimed iodine, powder it and then dry for twenty-four hours over calcium chloride. Keep the product in well-stoppered bottles, in a cool place. One Gm. of iodine, thus purified, leaves no weighable residue when sublimed.

Iodine Test Solution.—Dissolve 1 Gm. of iodine (see page 588) and 3 Gm. of potassium iodide (see page 902) in 50 mils of distilled water.

Iodo-bromide Test Solution.—(See Iodine Absorption Value Test No. 8.) Dissolve 13.2 Gm. of powdered iodine (see page 588) in 1000 mils of glacial acetic acid (see page 13) with the aid of a gentle heat, if necessary to facilitate solution. Cool the solution to 25° C. (77° F.) and determine the iodine content in 20 mils of the solution by means of tenth-normal sodium thiosulphate V.S.; then add to the solution a quantity of bromine (see page 1678) molecularly equivalent to that of the iodine present (3 mils being the usual approximate amount). Keep the solution in glass-stoppered bottles, protected from light.

Iron, Metallic, Fe.—Bright and perfectly clean iron in the form of wire, sheet, filings, or powder (electrolytically reduced). For making solutions of pure iron salts, fine, thin, bright wire (so-called "florist's" or "piano wire") is used. For detecting copper use bright pieces of sheet iron or steel needles.

Lævo-methylamino-ethanol-catechol, $C_9H_{13}O_3N$.—A nearly white to light brown micro-crystalline powder. Very slightly soluble in water; almost insoluble in alcohol (90 per cent.), in ether, and in chloroform. Combines with acids to form salts which are readily soluble in water and in alcohol (90 per cent). Melts, with partial decomposition, between 205° and 212° C. (401° and 413.6° F.). Alkaline to moistened litmus paper. A dilute, slightly acidified solution gives with a trace of ferric chloride an emerald-green color which is changed to purple or carmine by the cautious addition of a dilute solution of sodium hydroxide. It readily reduces solution of gold chloride and gradually develops a characteristic, unpleasant odor when a small quantity is mixed with five times its volume of sodium hydroxide T.S. It yields no precipitate with potassio-mercuric iodide T.S. (*absence of most alkaloids*). No weighable ash is obtained on ignition of 0.2 Gm.

Lead Acetate Glass Wool.—Immerse glass wool (see page 1682) in a mixture of equal parts of lead acetate T.S. and distilled water and remove the excess of liquid by pressing it between filter paper. Prepare the glass wool, as just described, immediately before it is required in the test.

Lead Acetate Test Paper.—Immerse strips of heavy white filter paper, 6 cm. in width and 8 cm. in length, in a mixture of equal parts of lead acetate T.S. and distilled water, drain off the excess of liquid and dry the paper on glass in an oven at 100° C. (212° F.), avoiding contact with metal.

Lead Acetate Test Solution.—Dissolve 10 Gm. of clear, transparent crystals of lead acetate (see page 872), free from adhering lead carbonate, in sufficient distilled water to measure 100 mils. Preserve the solution in well-stoppered bottles.

Lead Acetate Test Solution, Alcoholic.—Dissolve 3 Gm. of clear transparent crystals of lead acetate (see page 872), free from adhering lead carbonate, in sufficient alcohol to measure 100 mils. Preserve the solution in well-stoppered bottles.

Lead Acetate Test Solution, Basic.—Use the official solution of lead subacetate (see page 650).

Lead Nitrate, $Pb(NO_3)_2$.—Colorless, octahedral crystals, transparent or opaque. Soluble in 1.85 parts of water at 25° C. (77° F.), in 0.75 part of boiling water, and almost insoluble in alcohol. Lead nitrate responds to the tests of identity for lead and freedom from foreign metals directed under *Plumbi Acetas* (see page 872).

Lead Peroxide (Lead Dioxide), PbO_2.—A dark brown powder containing not less than 90 per cent. of lead peroxide. Insoluble in nitric acid; when warmed with hydrochloric acid, it is converted into lead chloride with the evolution of chlorine; when heated alone or with sulphuric acid, lead peroxide gives off oxygen. It is dissolved by concentrated solutions of potassium or sodium hydroxide. Dissolve by agitation about 0.5 Gm. of finely powdered lead peroxide, previously dried to constant weight at 100° C. (212° F.) and accurately weighed, in a solution of 1.5 Gm. of potassium iodide (see page 902) and 12 Gm. of sodium acetate (see page 1010), in 8 mils of glacial acetic acid (see page 13) diluted with an equal volume of distilled water. Should the resulting solution be turbid, add further small portions of sodium acetate until clear. Then determine the liberated iodine by titrating with tenth-normal sodium thiosulphate V.S., starch T.S. being used as indicator. It shows not less than 90 per cent. of PbO_2. Each mil of tenth-normal sodium thiosulphate V.S. is equivalent to 0.01195 Gm. of PbO_2.

Lime, Freshly Slaked.—To prepare freshly slaked lime for the Opium Assay, drop upon a convenient quantity of lime one-third of its weight of water, cover it and allow it to stand until the lime is slaked and cooled.

Litmus Paper and Test Solution.—See under *Indicators* (page 1708).

Magnesia Mixture Test Solution.—Dissolve 5.5 Gm. of magnesium chloride, and 7 Gm. of ammonium chloride (see page 133) in 65 mils of distilled water, add 35 mils of ammonia water (see page 166), set the mixture aside for a few days in a well-stoppered vessel, and filter. If not perfectly clear, filter the solution before using.

Magnesium Chloride, $MgCl_2+6H_2O$.—White, deliquescent crystals, soluble in about 0.6 per cent. of cold water and about 5 parts of alcohol, leaving no insoluble residue. Ten mils of an aqueous solution (1 in 20) shows no precipitate upon the addition of a few drops of diluted sulphuric acid (*barium*), nor after the addition of 10 mils of ammonium chloride T.S. followed by a few drops of ammonia water and 5 mils of ammonium oxalate T.S. (*calcium*), nor after the addition of ammonium sulphide T.S. (*heavy metals*).

Magnesium Sulphate Test Solution.—Dissolve 10 Gm. of magnesium sulphate (see page 677) in sufficient distilled water to measure 100 mils.

Manganese Sulphate, $MnSO_4$.—Containing from 4 to 5 molecules of water of crystallization (depending on the temperature at which it is crystallized), forming pale rose-red crystals, slightly efflorescent in the air, soluble in about 1 part of water, insoluble in alcohol. Its aqueous solution (1 in 20) yields with barium chloride T.S. a white precipitate insoluble in hydrochloric acid, and with ammonium sulphide T.S. a salmon colored precipitate. Dissolve 1 Gm. of the salt in 50 mils of distilled water, add 0.5 mil of hydrochloric acid (see page 33) and a few drops of chlorine water (see page 1679), boil for a few minutes and cool. On now adding 1 mil of potassium sulphocyanate T.S. to this solution no red color is produced. Dissolve 1 Gm. of the salt in 50 mils of distilled water, add about 10 mils of ammonium chloride T.S., heat to boiling, and precipitate the manganese with ammonium sulphide T.S., continuing the heating until the precipitate acquires a greenish color, then filter, evaporate the filtrate to dryness and ignite; not more than 0.5 per cent. of residue remains (*calcium, magnesium, or alkali metals*).

Manganese Sulphate Test Solution.—Dissolve 10 Gm. of manganese sulphate in 50 mils of distilled water, and add sufficient diluted sulphuric acid to make 100 mils.

Mercuric Bromide, $HgBr_2$.—White rhombic needles or prisms or lustrous scales or a granular, crystalline powder, fusing at about 325° C. (617° F.) and subliming without decomposition. Soluble in 200 parts of water at 25° C. (77° F.) and in 25 parts of boiling water; readily soluble in boiling alcohol.

Mercuric Bromide Test Paper.—Cut stiff, heavy quantitative filter paper (see Filter Paper, Quantitative, page 1681) into strips 3 mm. in width and about 12 cm. in length. Immerse these strips for five minutes in alcoholic mercuric bromide T.S. (see below). Remove the excess of solution by pressing the strips between filter paper and then dry them quickly on glass in an oven heated to 100° C. (212° F.). Place the strips at once in a wide-mouthed bottle and stopper it securely.

Mercuric Bromide Test Solution, Alcoholic.—Dissolve 5 Gm. of mercuric bromide in 100 mils of alcohol, employing a gentle heat to facilitate solution. Keep it in glass-stoppered bottles protected from the light.

Mercuric Chloride Test Solution.—Dissolve 5 Gm. of corrosive mercuric chloride (see page 552) in sufficient distilled water to measure 100 mils.

Mercuric Nitrate Test Solution, $Hg(NO_3)_2$.—Mix 45 Gm. of nitric acid (see page 48) with 15 mils of distilled water and dissolve 40 Gm. of red mercuric oxide (see page 562) in the mixture. Keep the solution in glass-stoppered bottles.

Mercuric Potassium Iodide Test Solution (Mayer's Reagent).— Dissolve 1.358 Gm. of corrosive mercuric chloride (see page 552) in 60 mils of distilled water, and 5 Gm. of potassium iodide (see page 902) in 10 mils of distilled water. Mix the two solutions, and then add sufficient distilled water to measure 100 mils.

Mercuric Potassium Iodide Test Solution, Alkaline (Nessler's Reagent).—Dissolve 10 Gm. of potassium iodide (see page 902) in 10 mils of distilled water, and add gradually in portions a saturated aqueous solution of corrosive mercuric chloride (see page 552) with constant agitation, until a slight red precipitate remains undissolved; to this mixture add 30 Gm. of potassium hydroxide (see page 899) and, when solution has taken place, 1 mil more of the saturated aqueous solution of mercuric chloride. Dilute this solution with distilled water until it measures 200 mils. Allow the precipitate to subside, and draw off the clear fluid. Two mils of this reagent, when added to 50 mils of distilled water containing 0.05 milligramme of ammonia, produces at once a yellowish-brown coloration.

Mercurous Nitrate Test Solution, $HgNO_3$.—Mix 10 Gm. of pure mercury (see page 565) with 5 mils of nitric acid (see page 48) and 5 mils of distilled water, in a porcelain evaporating dish and set it aside for twenty-four hours in a cool, dark room. Separate and drain the crystals of mercurous nitrate, and dissolve them in 100 mils of distilled water. Preserve the solution in a dark amber-colored bottle in which a small quantity of mercury has been placed.

Methyl Orange and Methyl Orange Test Solution.—See under *Indicators* (page 1708).

Methyl Red and Methyl Red Test Solution.—See under *Indicators* (page 1708).

Methyl Violet 6B (Paris Violet 6B).—A mixture of penta- and hexa-methyl-para-rosaniline chlorides. A very dark greenish powder which dissolves readily in water or alcohol, yielding a deep violet solution. Its solution in alcohol or chloroform has a deeper blue color than the aqueous solution. Insoluble in ether. An aqueous solution of methyl violet (1 in 500) when added drop by drop to tannic acid T.S. forms a deep blue precipitate (*basic color*). The addition of a few drops of hydrochloric acid to a mixture of about 0.5 Gm. of zinc dust and 5 mils of an aqueous solution of methyl violet (1 in 500) causes rapid decolorization. Place a few drops of this decolorized solution near a few drops of ammonia water on filter paper; the zone of contact assumes a blue color. Add hydrochloric acid slowly, drop by drop, with agitation, to an aqueous solution of the salt (1 in 500); the violet color gradually changes to blue-green, green and finally to brownish-yellow, the solution remaining clear. Upon gradually diluting this solution with distilled water, the color changes take place in the reverse order. Add 5 mils of sodium hydroxide T.S. to 5 mils of an aqueous solution of methyl violet (1 in 500); a blue precipitate gradually forms and upon heating, the mixture becomes colorless and deposits white floccules. Concentrated sulphuric acid dissolves methyl violet with an orange to brownish-red color; upon slowly diluting this solution with distilled water, the solution assumes a brown, then green, and finally a blue color. Incinerate 1 Gm. of methyl violet; not more than 0.01 Gm. of ash remains.

Methylene Green (Mono-nitro-methylene blue, Tetra-methyl-mono-nitro-thionin-chloride), $(CH_3)_2 N.C_6H_3 : N(S)C_6H_2(NO_2).N.(CH_3)_2Cl$.—A very dark brown to gray-black powder; soluble in water and slightly soluble in alcohol, yielding greenish-blue solutions. An aqueous solution of methylene green (1 in 500) yields a precipitate upon the addition of tannic acid T.S. The addition of 0.5 Gm. of zinc dust and

5 mils of ammonia water to 10 mils of an aqueous solution of the salt (1 in 500) and warming the resulting mixture causes decolorization. Add a few drops of solution of hydrogen dioxide to the decolorized liquid, keeping the solution alkaline; a violet color is produced. The addition of hydrochloric acid to an aqueous solution of methylene green (1 in 500) produces no change; sodium hydroxide T.S. produces a violet precipitate which dissolves upon heating (distinction from *methylene blue*). Methylene green dissolves in sulphuric acid with a green color and on cautiously diluting this solution with distilled water it changes to greenish-blue.

Molybdic Acid, H_2MoO_4.—A white to yellowish-white powder, containing about 85 per cent. of molybdic anhydride (MoO_3). One Gm. of molybdic acid yields a clear solution with 10 mils of ammonia water; the addition of an equal volume of hydrogen sulphide T.S. produces a greenish-yellow color but no brownish-yellow color or precipitate (*heavy metals*). Pour a solution of 10 Gm. of molybdic acid in about 25 mils of ammonia water into a mixture of 75 parts of nitric acid (see page 48), and 75 parts of distilled water and set it aside for twelve hours at about 40° C. (104° F.); no yellow precipitate appears (*phosphoric acid*). Prepare a solution of about 0.5 Gm. of molybdic acid, accurately weighed, in 50 mils of distilled water by the aid of about 3 mils of ammonia water, warming it to facilitate solution. Make this solution acid with acetic acid, dilute it further with 200 mils of distilled water, and heat to boiling; then add 30 mils of an aqueous solution (1 in 20), containing lead acetate (see page 872), cover the beaker and boil the liquid for several minutes, stirring occasionally to facilitate granulation of the precipitate. Wash the precipitate by decantation ten times, using 50 mils of boiling distilled water each time; collect the precipitate in a previously ignited and tared Gooch crucible containing a layer of asbestos (see page 1677), again wash the precipitate with boiling distilled water until the washings cease to react with hydrogen sulphide T.S., and ignite to constant weight. The amount of lead molybdate ($PbMoO_4$) obtained, multiplied by 0.39226, gives the amount of molybdic anhydride (MoO_3) present.

Naphthylamine (Alpha) Hydrochloride, $C_{10}H_7.NH_2.HCl$.—A white crystalline powder which turns bluish on exposure. Soluble in water, alcohol, or ether. For tests of identity see below, under Betanaphthylamine.

Naphthylamine (Alpha) Hydrochloride Test Solution.—Boil 0.5 Gm. of alpha-naphthylamine hydrochloride with 100 mils of distilled water, for ten minutes, keeping the volume constant and finally filter it through cotton. Employ only freshly distilled water in preparing this reagent, which must be kept in well-stoppered bottles, protected from light.

Naphthylamine (Beta) Hydrochloride, $C_{10}H_7.NH_2.HCl$.—White to yellowish, glossy scales, or flakes, soluble in about 50 parts of water and readily soluble in alcohol. The addition of one drop of ferric chloride T.S. to 10 mils of an aqueous solution of betanaphthylamine hydrochloride (1 in 100) does not produce a violet color (*alpha-naphthylamine*); the addition of a small crystal of sodium nitrite to an aqueous solution of betanaphthylamine hydrochloride (1 in 100) produces an orange precipitate, not a dark red precipitate (distinction from *alpha-naphthylamine*).

Nitric Acid, HNO_3.—Use the official nitric acid (see page 48).

Nitric Acid, Diluted.—Add 50 Gm. of nitric acid (see page 48) to 290 Gm. of distilled water. It contains not less than 9.5 per cent. nor more than 10.5 per cent. of HNO_3. Diluted nitric acid to which an equal volume of distilled water has been added is not affected upon the addition of barium nitrate T.S. (*sulphuric acid*), or of silver nitrate T.S. (*hydrochloric acid*). Dilute about 20 mils of diluted nitric acid, accurately weighed, with 10 mils of distilled water and titrate with normal potassium hydroxide V.S., methyl orange T.S. being used as indicator. It shows not less than 9.5 per cent. nor more than 10.5 per cent. of HNO_3.

Nitric Acid, Fuming.—Use the commercial red fuming acid, if it is of a specific gravity between 1.48 and 1.52 at 25° C. (77° F.). Preserve it carefully in glass-stoppered bottles, in a cool place. It should conform to the tests for purity given under *Acidum Nitricum*.

Oil of Cedarwood (for use with the microscope).—For clearing microscopic sections, a selected commercial distilled oil from the wood of the Red Cedar, *Juniperus Virginiana* Linné (Fam. *Pinaceæ*) should be used. Such oil should have a refractive index of about 1.504 at 20° C. (68° F.). For use with homogeneous immersion lenses, a specially prepared oil is required, having a refractive index of exactly 1.515 at 18° C. (64.4° F.).

Orange G (The sodium salt of azo-benzene-beta-naphthol disulphonic acid), $C_6H_5.N : N.C_{10}H_4(OH)(SO_3Na)_2(2.6.8)$.—Orange to brick-red powder, or dark red crystals; readily soluble in water, yielding an orange-yellow solution, slightly soluble in alcohol, insoluble in ether or chloroform. The addition of tannic acid T.S. to an aqueous solution of orange G (1 in 500) causes no precipitation (*acid color*). The addition of hydrochloric acid to a mixture of 0.5 Gm. of zinc dust and 10 mils of an aqueous solution of the color (1 in 500) produces decolorization. When filtered, the colorless filtrate, on standing exposed to the air does not regain its original color (presence of *azo-group*). When heated, orange G does not deflagrate (distinction from *nitro colors*). The addition of barium or calcium chloride T.S. to a concentrated aqueous solution of orange G produces a colored, crystalline precipitate. The addition of hydrochloric acid to an aqueous solution of the dye (1 in 500) produces no change; the addition of sodium hydroxide T.S. to a similar solution produces a yellowish-red to a bordeaux color but no precipitation. Orange G dissolves in concentrated sulphuric acid with an orange to yellowish-red color; no change in color results upon diluting the solution cautiously with distilled water.

Orcin (Orcinol; Dihydroxy-methyl-benzene 1.3.5.), $C_6H_3(CH_3).(OH).(OH).+H_2O$.—In the form of monoclinic prisms, white with a reddish tint, which fuse at about 58° to 60° C. (136.4° to 140° F.). Orcin has an intensely sweet and astringent taste; very soluble in hot water, less soluble in cold water, readily soluble in alcohol or ether. The anhydrous substance fuses between 106° and 108° C. (222.8° and 226.4° F.). Anhydrous crystals are deposited from an ether solution. When exposed to light or air the crystals assume a reddish-brown color. The addition of a few drops of ferric chloride T.S. to an aqueous solution of orcin (1 in 20) produces a deep blue color. Warm 10 mils of an aqueous solution of orcin (1 in 10) with 10 mils of sodium hydroxide T.S. and add a few drops of chloroform; the solution assumes a purple-red color then bright red, and, after diluting with distilled water, shows an intense, greenish-yellow fluorescence. Aqueous solutions of orcin (1 in 20) tested separately do not yield precipitates upon the addition of test

solutions of either mercuric chloride, cupric sulphate, tannic acid or lead acetate; with basic lead acetate T.S., a white precipitate is obtained (characteristic of *resorcinol derivatives*). Dissolve about 1.3 Gm. of orcin, accurately weighed, in sufficient distilled water to measure 1000 mils. Introduce 25 mils of this solution, 25 mils of tenth-normal bromine V.S. and 50 mils of distilled water into a glass-stoppered flask of about 300 mils capacity, and then add 25 mils of dilute sulphuric acid T.S. After thoroughly agitating the mixture, set it aside for ten minutes, then cautiously lift the stopper, quickly introduce 2 Gm. of potassium iodide and close the flask at once. Agitate the solution and, after five minutes, determine the liberated iodine by means of tenth-normal sodium thiosulphate V.S.; conduct a blank experiment, omitting the addition of the solution of orcin and note the number of mils of tenth-normal sodium thiosulphate V.S. consumed. The difference in mils of tenth-normal sodium thiosulphate V.S. required in the original titration and the blank test, when multiplied by 0.002068, gives the quantity of anhydrous orcin present, which corresponds to not less than 85 per cent.

Ouabain.—Crystallized ouabain, frequently, though erroneously, referred to as crystallized strophanthin, or g-strophanthin Thoms. Ouabain is a glucoside, $C_{30}H_{46}O_{12}+9H_2O$, obtained from the wood of *Acocanthera Ouabaio* Cathelineau, or from the seed of *Strophanthus gratus* Franchet. It occurs as colorless, quadratic crystals of bitter taste. It is easily soluble in hot water, soluble in 100 parts of cold water and in about 30 parts of dehydrated alcohol and in 30 parts of amyl alcohol; slightly soluble in acetic ether, ether or chloroform. A solution of 0.01 Gm. of ouabain in 1 mil of distilled water, poured over a layer of concentrated sulphuric acid colors the latter from pink to red and the aqueous layer is colored green. Heated to 105° C. (221° F.), it loses about 20 per cent. of water. The ouabain thus dried melts between 187° and 188° C. (368.6° and 370.4° F.). On igniting 0.2 Gm. no weighable ash remains. Heating with diluted hydrochloric or sulphuric acid produces hydrolytic cleavage, yielding a body which is identical with rhamnose.

Oxalic Acid, Purified, $H_2C_2O_4+2H_2O$.—Colorless, uneffloresced crystals, soluble in 10 parts of cold water, in about 3 parts of boiling water and in 2.5 parts of alcohol. Ten Gm. when ignited leaves not more than 0.005 Gm. of residue (*non-volatile matter*). Dissolve 2 Gm. of oxalic acid and about 3 Gm. of potassium hydroxide in 30 mils of distilled water, add to this solution about 15 drops of Nessler's Reagent (see page 1684), no brownish-red coloration develops when compared with a blank test, omitting the oxalic acid (*ammonium compound*). Preserve it in well-stoppered bottles.

Oxalic Acid Test Solution.—Dissolve 5 Gm. of purified oxalic acid (see above) in sufficient distilled water to measure 100 mils.

Palladous Chloride, $PdCl_2$.—A dark brown, hygroscopic mass, readily soluble in water.

Palladous Chloride Test Solution.—Dissolve 0.5 Gm. of palladous chloride in sufficient distilled water to measure 10 mils. Preserve the solution in a glass-stoppered bottle.

Paradimethylaminobenzaldehyde (Dimethyl-p-amino-benzaldehyde), $(CH_3)_2N.C_6H_4.CHO$.—Colorless scales fusing at 73° C. (163.4° F.); soluble in hot water. The addition of an alcoholic solution of benzidine (1 in 100) to a slightly acidified solution of paradimethylaminobenzaldehyde produces a brick-red precipitate after standing.

Peptone (Beef Peptone).—The dried product of the pancreatic digestion of meat. A yellow powder of a slightly bitter but not disagreeable taste and an odor resembling that of meat extract. Soluble in all proportions in water, yielding a yellowish-brown liquid of faintly acid reaction. Slightly soluble in diluted alcohol, insoluble in alcohol or ether. An aqueous solution of peptone (1 in 20), upon the addition of tannic acid T.S. or mercuric chloride T.S., yields a precipitate. On the addition of 0.5 mil of potassium hydroxide T.S. to an aqueous solution of peptone (1 in 20), followed by a solution of copper sulphate (1 in 50), added drop by drop with agitation, an intense, red-violet color is produced (biuret reaction). Pour an aqueous solution of peptone (1 in 20) into an excess of alcohol, allow the resulting precipitate to settle and decant the clear supernatant liquid; the residue left on evaporating this liquid is completely soluble in alcohol and no coagulation occurs. One Gm. of peptone dissolves in 20 parts of water with but slight turbidity. When an aqueous solution of peptone (1 in 200) is heated to boiling, no precipitation occurs; the addition of nitric acid does not cause turbidity (*coagulable albumin*). Saturate an aqueous solution of peptone (0.5 Gm. in 20 mils) with powdered zinc sulphate; not more than a slight flocculent precipitate appears (*proteoses*). Dry 1 Gm. of peptone at 100° C. (212° F.), it loses not more than 7 per cent. in weight; ignite this dried product; not more than 0.005 Gm. of ash remains. Peptone contains not less than 12.5 per cent. of nitrogen when determined by the Kjeldahl method, corresponding to about 78 per cent. of pure peptone.

Phenoldisulphonic Acid Test Solution (Phenol-disulphonic acid), $C_6H_3(OH)(SO_3H)_2$.—Mix 37 parts of sulphuric acid (see page 64) with 3 parts of phenol (see page 838) in a flask of suitable capacity and heat in a bath of boiling water for six hours. Transfer the product to a glass-stoppered bottle while still fluid, and when desired for use, warm on a water bath until liquefied.

Phenolphthalein Test Solution.—See under *Indicators* (page 1709).

Phenylhydrazine, $C_6H_5.NH.NH_2$.—A colorless, or slightly yellowish, highly refractive liquid, boiling between 241° and 243° C. (465.8° and 469.4° F.), congealing, when cold, to monoclinic plates fusing at about 19° C. (66.2° F.). Phenylhydrazine is slightly soluble in cold water, more soluble in hot water and readily soluble in alcohol or ether. Its solutions rapidly absorb oxygen from the air, becoming brown. Shake 2 mils of phenylhydrazine with 20 mils of 5 per cent. acetic acid; a clear solution results.

Phenylhydrazine Dihydrochloride, $C_6H_5NH.NH_2.2HCl$.—A white crystalline powder, readily soluble in water, but slowly soluble in alcohol. It melts at about 200° C. (392° F.). Add to an aqueous solution of phenylhydrazine dihydrochloride (1 in 10) sufficient sodium hydroxide T.S. until the reaction is alkaline; upon the addition of copper sulphate T.S., a dense red precipitate is formed. An aqueous solution of the salt (1 in 20) has an acid reaction and is clear and colorless. One Gm. of the salt when ignited leaves no weighable residue.

Phenylhydrazine Hydrochloride, $C_6H_5.NH.NH_2.HCl$.—Silky scales melting at about 225° C. (437° F.). Readily soluble in water or alcohol. Its aqueous solution is clear and free from suspended particles.

Phloroglucinol, $C_6H_3(OH)_3+2H_2O$—A white to cream colored crystalline powder, readily soluble in water, alcohol, or ether. When rapidly heated, it melts between 217° and 219° C. (422.6° and 426.2° F.),

or when slowly heated, between 200° and 209° C. (392° and 408.2° F.). Introduce a few crystals of phloroglucinol in a test tube with about 1 mil each of sulphuric acid and acetic anhydride and heat in boiling water for from five to ten minutes; no blue color develops (*diresorcinol*).

Phloroglucinol Test Solution.—Prepare a 3 per cent. solution of phloroglucinol in alcohol. Keep the solution protected from light.

Phosphotungstic Acid, $P_2O_5.24WO_3+xH_2O$.—White to yellowish-green crystals efflorescing slightly in air. Readily soluble in water or alcohol and slightly soluble in ether. To a solution of 1 Gm. of phosphotungstic acid in 10 mils of distilled water, add 0.1 Gm. of sodium chloride and about 3 drops of indigo T.S. followed by about 10 mils of sulphuric acid, cautiously added; then allow the liquid to stand for ten minutes, the blue color does not disappear (*nitrate*). When 1 Gm. of phosphotungstic acid is dissolved in 10 mils of distilled water and boiled, and a small piece of sodium hydroxide added (about 2 Gm.) and the solution warmed, ammonia is not evolved (*ammonium salts*).

Picric Acid Test Solution.—See page 1692.

Platinic Chloride (Chloroplatinic Acid), $H_2PtCl_6+6H_2O$.—A brownish-red, hygroscopic, crystalline mass, soluble in water, alcohol, or ether, with a yellow color. One Gm. is completely soluble in 10 mils of dehydrated alcohol. Its aqueous solution should be yellow and not brownish. When platinic chloride is strongly ignited in a porcelain crucible, not less than 37.6 per cent. of residue remains. Digest this residue with about ten times its weight of a mixture of five volumes of nitric acid and ten volumes of distilled water on a water bath for fifteen minutes, filter, evaporate to dryness and ignite to constant weight; a residue not exceeding 0.15 per cent. of the platinic chloride taken remains (*other metals*).

Platinic Chloride Test Solution.—Dissolve 2.6 Gm. of platinic chloride in 20 mils of distilled water.

Potassio-Mercuric Iodide Test Solution.—See page 1684.

Potassium Bitartrate, $KHC_4H_4O_6$.—Purify potassium bitartrate (see page 887), to render it suitable for standardizing volumetric solutions of potassium and sodium hydroxide, as follows: To 100 Gm. of the salt, contained in a beaker, add a mixture of 85 mils of distilled water and 25 mils of diluted hydrochloric acid; place the covered beaker on a water bath and digest the mixture, with occasional stirring for three hours. Quickly cool the mixture, drain the solution from the precipitate, wash the latter by affusion and decantation with two successive portions of 100 mils each of distilled water, collect the precipitate on a plain filter, and continue the washing with cold distilled water until the filtrate, after adding a few drops of nitric acid, ceases to become opalescent upon the addition of silver nitrate T.S. Then dissolve the precipitate of potassium bitartrate in the smallest possible volume of boiling distilled water (about 1500 mils), filter, and constantly stir the filtrate while being rapidly cooled. When the mixture is cold, collect the crystalline precipitate on a plain filter, wash it with 300 mils of cold distilled water, and, after thoroughly draining, dry it at 120° C. (248° F.) until of constant weight. Preserve it in dry, securely stoppered bottles. Purified potassium bitartrate is employed for standardizing normal and tenth-normal potassium and sodium hydroxide V.S.

Potassium Bromate, $KBrO_3$.—White cubical crystals or a granular crystalline powder, having a pungent, saline taste. Soluble in 15.5 parts of water at 25° C. (77° F.), and in 2 parts of boiling water, slightly soluble in alcohol. An aqueous solution has a neutral reaction, and does not at once produce a yellow color upon the addition of diluted sulphuric acid (*bromide*). When heated to 350° C. (662° F.), the salt undergoes decomposition with the evolution of oxygen. Potassium bromate should not be triturated or heated with organic or easily oxidizable substances. The addition of nitric acid or sulphuric acid to the salt causes decomposition with the evolution of bromine. Dissolve 0.1 Gm. of potassium bromate, dried at 100° C. (212° F.) and 3 Gm. of potassium iodide, in about 25 mils of distilled water contained in a glass-stoppered bottle of suitable size, and, after the addition of 5 mils of hydrochloric acid, stopper the bottle securely, and set aside for ten minutes. Not less than 35.85 mils of tenth-normal sodium thiosulphate V.S. is required to discharge the color, corresponding to 99.8 per cent. of $KBrO_3$.

Potassium Carbonate Test Solution.—Heat about 15 Gm. of potassium carbonate (see page 892) in a crucible, gradually raising the temperature to 130° C. (266° F.), cool it in a desiccator, weigh off 10 Gm. of the residue, and dissolve it in sufficient distilled water to measure 100 mils.

Potassium Chromate, K_2CrO_4.—Yellow rhombic crystals, soluble in 1.6 parts of water, insoluble in alcohol. Add a few drops of silver nitrate T.S. to 10 mils of an aqueous solution of the salt (1 in 10) followed by 10 mils of nitric acid, and warm to about 50° C. (122° F.), no turbidity appears (*chloride*). Another 10 mils of a solution of the same strength when mixed with an equal volume of diluted hydrochloric acid does not become turbid after the addition of barium chloride T.S. (*sulphate*). Ten mils of an aqueous solution of salt (1 in 10) does not become turbid upon the addition of 5 mils of ammonia water, followed by 2 mils of ammonium oxalate T.S. (*alkali earths*). A solution of 0.1 Gm. of the salt in 20 mils of distilled water does not become red upon the addition of a few drops of phenolphthalein T.S. (*free alkali*).

Potassium Chromate Test Solution.—Dissolve 10 Gm. of potassium chromate in sufficient distilled water to measure 100 mils.

Potassium Dichromate, Purified (Potassium Bichromate), $K_2Cr_2O_7$.—This salt must conform to the following tests before it can be used in the preparation of the tenth-normal volumetric solution: To a solution of 5 Gm. of the salt in 100 mils of distilled water, add 30 mils of concentrated hydrochloric acid (see page 1682), followed by 5 mils of barium chloride T.S.; no turbidity appears after standing twelve hours (*sulphate*). To a solution of 5 Gm. of the salt in 60 mils of distilled water add 1 mil of ammonium chloride T.S. followed by ammonia water until alkaline (about 10 mils) and boil the liquid; no precipitation takes place after standing twelve hours (*aluminum*). The further addition of ammonium oxalate T.S. to the solution, which should still be alkaline, produces neither turbidity nor the slightest precipitation after standing twelve hours (*alkali earths*). Add 10 mils of nitric acid to a solution of 1 Gm. of the salt in 20 mils of distilled water and heat it to about 50° C. (122° F.); no turbidity develops within five minutes after the addition of a few drops of silver nitrate T.S. (*chloride*).

Potassium Dichromate Test Solution.—Dissolve 10 Gm. of purified potassium dichromate in sufficient distilled water to measure 100 mils.

Potassium Ferricyanide, $K_3Fe(CN)_6$.—Dark red crystals soluble in about 2.5 parts of cold water and in 1.5 parts of boiling water. Its aqueous solution undergoes decomposition upon standing, hence its solu-

tions must be freshly made when required for use. Potassium ferricyanide when added to ferrous salts yields a blue precipitate (Turnbull's Blue); when added to solutions of ferric salts it yields clear brown solutions.

Potassium Ferricyanide Test Solution.—Dissolve 1 part of potassium ferricyanide in about 10 parts of distilled water. This solution should be freshly made when required, as it undergoes decomposition with formation of ferrocyanide on standing. A freshly prepared aqueous solution mixed with ferric chloride T.S. which has been well diluted with distilled water shows a brown tint, free from turbidity or a shade of green.

Potassium Ferrocyanide, $K_4Fe(CN)_6+3H_2O$.—Yellow, soft, transparent crystals which are slightly efflorescent on exposure to air. Readily soluble in hot or cold water, insoluble in alcohol. A freshly prepared aqueous solution of the salt (1 in 20) is neutral to litmus; such a solution yields a blue precipitate with solutions of ferric salts, a reddish-brown precipitate with copper sulphate T.S., and a white precipitate with lead acetate T.S. or silver nitrate T.S.

Potassium Ferrocyanide Test Solution.—Dissolve 10 Gm. of potassium ferrocyanide in sufficient distilled water to measure 100 mils.

Potassium Hydroxide Test Solution.—Use the official solution of potassium hydroxide (see page 654).

Potassium Hydroxide Test Solution, Alcoholic.—Use the half-normal alcoholic potassium hydroxide V.S. (see page 1698).

Potassium Hydroxide Test Solution, Special.—This solution is to be prepared of the same strength as *Liquor Potassii Hydroxidi*, employing potassium hydroxide which, in addition to the tests prescribed under *Potassii Hydroxidi*, complies with the following: Dissolve 1 Gm. of the potassium hydroxide in 20 mils of distilled water, in a test tube about 2 cm. in diameter, add 5 mils of nitric acid, followed by a few drops of silver nitrate T.S.; not more than a slight opalescence is produced.

Potassium Iodide Test Solution.—Dissolve 20 Gm. of potassium iodide (see page 902) in sufficient distilled water to measure 100 mils, and preserve the solution in dark, amber-colored, well-stoppered bottles. The solution should be frequently renewed.

Potassium Nitrate, KNO_3.—In addition to the tests prescribed for Potassii Nitras (see page 905), this salt, for use as a reagent, must conform to the following tests: To a solution of 1 Gm. of potassium nitrate in 20 mils of distilled water, add 1 mil of nitric acid followed by a few drops of silver nitrate T.S.; no opalescence results (*chloride*). To a solution of 2 Gm. of the salt in 50 mils of distilled water, add 1 mil of hydrochloric acid, followed by barium chloride T.S.; no precipitate forms after standing for several hours (*sulphate*).

Potassium Permanganate Test Solution, $KMnO_4$.—Use the tenth-normal potassium permanganate V.S. (see page 1700).

Potassium Sulphate, K_2SO_4.—Hard, colorless, transparent prisms, or a white powder, odorless and having a somewhat bitter saline taste; permanent in the air. Soluble in about 9 parts of water at 25° C. (77° F.) and in 4 parts of boiling water. A saturated aqueous solution of the salt, which is neutral to litmus, yields a white, crystalline precipitate with an excess of sodium bitartrate T.S. An aqueous solution of the salt (1 in 20) yields with barium chloride T.S. a heavy white precipitate, insoluble in hydrochloric acid. An aqueous solution of potassium sulphate (1 in 20), slightly acidulated with hydrochloric acid, does not respond to the Test for heavy metals (see Test No. 3). Five mils of an aqueous solution of the salt (1 in 30) does not exceed the limit for arsenic when subjected to the Test for arsenic (see Test No. 1).

Potassium Sulphate Test Solution.—Dissolve 1 Gm. of potassium sulphate in sufficient distilled water to measure 100 mils.

Potassium Sulphocyanate (Potassium Thiocyanate), KCNS.—Colorless, hygroscopic, prismatic crystals. Readily soluble in less than its own weight of water; soluble in 10 parts of boiling dehydrated alcohol, yielding a clear solution. An aqueous solution of the salt (1 in 20) does not become turbid upon the addition of a few drops of concentrated hydrochloric acid (see page 1682), followed by barium chloride T.S. (*sulphate*). An aqueous solution of the salt (1 in 20), after the addition of 1 mil of diluted hydrochloric acid, remains colorless (*iron*), and does not respond to the Test for heavy metals (see Test No. 3).

Potassium Sulphocyanate Test Solution.—Use the tenth-normal potassium sulphocyanate V.S. (see page 1701).

Pyrogallol Test Solution, Alkaline.—Dissolve 0.5 Gm. of pyrogallol (see page 923) in 2 mils of distilled water and 12 Gm. of potassium hydroxide (see page 899) in 8 mils of distilled water. Mix the solutions immediately before using.

Resorcinol Test Solution.—Dissolve 1 Gm. of resorcinol (see page 947) in sufficient concentrated hydrochloric acid (see page 1682) to make 100 mils.

Rosaniline, Acetate, $C_{19}H_{18}N_3.C_2H_4O_2$.—The acetate of rosaniline (see *Fuchsin*, page 1681). Rosaniline acetate complies with all of the tests of identity and purity given under *Fuchsin*.

Rosolic Acid and Rosolic Acid Test Solution.—See under *Indicators* (page 1709).

Sawdust, Purified.—Moisten 1000 Gm. of oak sawdust, in approximately No. 20 powder, with water, pack in a cylindrical percolator and pour on enough of a 1 per cent. solution of sodium hydroxide to saturate the powder and leave a stratum above it.

When the liquid drops from the percolator, close the lower orifice and macerate the sawdust during twenty-four hours. Then proceed to percolate slowly until the alkaline percolate measures 5000 mils. Now continue the percolation with 4000 mils of 1 per cent. hydrochloric acid and then with water until the acid is all removed and the percolate is neutral. Finally dry the powder.

Selenous Acid, H_2SeO_3.—Colorless, prismatic or granular crystals, efflorescent in dry air and hygroscopic in moist air; readily soluble in water or alcohol. Red amorphous selenium is precipitated from aqueous solutions of selenous acid upon the addition of stannous chloride T.S. or sulphurous acid.

Silver Ammonium Nitrate Test Solution.—Dissolve 1 Gm. of silver nitrate (see page 182) in 20 mils of distilled water, and add ammonia water, drop by drop, agitating the mixture, until the precipitate first produced is almost, but not entirely, redissolved. Filter the solution and preserve it in dark amber-colored and well-stoppered bottles.

Silver, Metallic, Ag.—In the form of foil, wire or powder. Dissolve 2 Gm. of the metal in the smallest

possible quantity of nitric acid (see page 45) previously mixed with an equal volume of distilled water; no residue remains and the solution, after warming to remove the oxides of nitrogen, and diluting with fifty volumes of distilled water, remains colorless and clear. Add sufficient hydrochloric acid to this solution heated to boiling to precipitate the silver, filter, evaporate the filtrate to dryness and gently ignite the residue; not more than 0.0005 Gm. of residue remains (*foreign metals*), allowance being made for the non-volatile matter present in the water, reagents and extracted from the filter paper.

Silver Nitrate Test Solution.—For ordinary purposes, use the tenth-normal silver nitrate V.S. (see page 1702).

Silver Sulphate, Ag_2SO_4.—Small, white, anhydrous, lustrous rhombic crystals soluble in about 87 parts of cold water. It should correspond to the tests for purity given under *Argenti Nitras* (see page 183).

Silver Sulphate Test Solution.—Mix 1 Gm. of silver sulphate with 100 mils of distilled water in a glass-stoppered bottle and shake the mixture thoroughly. Decant the clear liquid when required for use. Alternative process: Dissolve 1 Gm. of silver nitrate (see page 182) in 0.5 mil of warm distilled water, and add 1.5 mils of sulphuric acid (see page 64); on cooling, small transparent crystals of silver sulphate, Ag_2SO_4, separate. Pour off the acid liquid carefully, wash the crystals repeatedly by decantation with cold distilled water, transfer them to a bottle, add 100 mils of distilled water, and shake thoroughly until the liquid is saturated. For use, decant a sufficient quantity of the solution.

Sodium Acetate, Anhydrous, CH_3COONa.—Heat sodium acetate (see page 1010) gently in a porcelain dish until fusion takes place and the salt becomes a pasty mass, then gradually increase the temperature, with caution, stirring constantly, until it again fuses, and continue the heat until a dry powder results. Care must be taken to avoid charring and the salt must be constantly stirred to prevent the adhesion of the mass to the sides of the dish.

Sodium Acetate Test Solution.—Dissolve 10 Gm. of sodium acetate (see page 1010) in sufficient distilled water to measure 100 mils.

Sodium Bisulphite, $NaHSO_3$.—It contains not less than 90 per cent. of $NaHSO_3$. Opaque, prismatic crystals, or a granular powder, having the odor of sulphur dioxide, and a disagreeable, sulphurous taste. Exposed to the air, the salt loses sulphur dioxide, and is gradually oxidized to sulphate. Soluble in 3.5 parts of water, and in 70 parts of alcohol at 25° C. (77° F.). Dissolve 1 Gm. of sodium bisulphite in 10 mils of diluted nitric acid and heat the solution sufficiently to expel the gases; the liquid does not become turbid (*thiosulphate*). Dissolve 1 Gm. of the salt in 20 mils of diluted hydrochloric acid, and heat it sufficiently to expel the sulphur dioxide; the remaining solution, after being restored to its original volume, does not respond to the Test for heavy metals (see Test No. 3). Transfer about 0.2 Gm. of sodium bisulphite, accurately weighed, to a glass-stoppered flask containing 50 mils of tenth-normal iodine V.S., and allow to stand with occasional agitation, until the salt is dissolved. Then titrate the excess of iodine with tenth-normal sodium thiosulphate V.S. It shows not less than 90 per cent. of $NaHSO_3$. Each mil of tenth-normal iodine V.S. corresponds to 0.005204 Gm. of $NaHSO_3$.

Sodium Bisulphite Test Solution.—Dissolve 30 Gm. of sodium bisulphite in sufficient distilled water to measure 100 mils. Should the solution possess a strong odor of sulphur dioxide, add a 20 per cent. aqueous solution of sodium hydroxide, drop by drop, until the odor becomes scarcely perceptible. The solution must be freshly prepared when needed.

Sodium Bitartrate, $NaHC_4H_4O_6+H_2O$.—White rhombic crystals or powder, soluble in 9 parts of cold and 1.8 parts of boiling water. When assayed and tested as directed under *Potassii Bitartras* (see page 887), it complies with the standards of purity there required. One mil of normal potassium hydroxide V.S. corresponds to 0.19006 Gm. of sodium bitartrate ($NaHC_4H_4O_6+H_2O$).

Sodium Bitartrate Test Solution.—Dissolve about 9 Gm. of sodium bitartrate in 100 mils of distilled water. Alternative method: To a solution of 3.5 Gm. of tartaric acid (see page 78) in about 80 mils of boiling distilled water, add gradually in small portions monohydrated sodium carbonate (see page 1023) until the solution has a neutral reaction to litmus paper. To the solution add 3.5 Gm. of tartaric acid, filter, and add sufficient distilled water to make the solution measure 100 mils. This solution must be freshly prepared when required.

Sodium Carbonate.—Use monohydrated sodium carbonate (see page 1023).

Sodium Carbonate, Anhydrous, Na_2CO_3.—This is prepared from sodium bicarbonate (see page 1014) which, in addition to the official requirements for purity, must conform to the following more rigorous tests before it can be employed for standardizing volumetric solutions of hydrochloric and sulphuric acids.

To a filtered solution of 5 Gm. of sodium bicarbonate in 100 mils of distilled water add an excess (5 mils) of concentrated hydrochloric acid (see page 1682), heat it to boiling, and then add 1 mil of barium chloride T.S. No cloudiness or precipitate forms within twelve hours (*sulphate*). To a solution of 1 Gm. of the bicarbonate in 30 mils of distilled water add 3 mils of nitric acid (see page 45); the solution remains clear, now heat it to boiling, and add 1 mil of silver nitrate T.S.; no opalescence appears within fifteen minutes (*chloride*). To 10 Gm. of sodium bicarbonate and about 50 mils of distilled water contained in a beaker of about 250 mils capacity, add slowly with stirring, about 30 mils of concentrated hydrochloric acid (see page 1682), taking care to avoid loss through violent effervescence. Filter, wash the beaker and filter with distilled water, transfer the filtrate and washings to a platinum dish, evaporate to dryness on a water bath and dry the residue for four hours at 120° C. (248° F.). Now add to the dried residue about 20 mils of distilled water and about 5 mils of concentrated hydrochloric acid (see page 1682), again evaporate to dryness and dry as before. Finally dissolve the residue in 3 mils of concentrated hydrochloric acid (see page 1682) and 50 mils of distilled water; the resulting solution remains perfectly clear upon standing (*silica*). To a solution of 1 Gm. of the bicarbonate in 15 mils of distilled water, add 2 mils of concentrated hydrochloric acid (see page 1682) followed by 2 drops of nitric acid (see page 45) and boil the solution; it is not reddened upon the addition of potassium sulphocyanate T.S., a blank test being carried out at the same time (*iron*).

Take any suitable quantity of sodium bicarbonate complying with the foregoing tests, place it in a platinum vessel and heat it in an air or sand bath for one-half hour at from 270° to 280° C. (518° to 536° F.) (not over 300° C. (572° F.)). Finally cool the salt in a desiccator and, before it is quite cold, transfer it to a dry, glass-stoppered bottle.

Sodium Carbonate Test Solution.—Dissolve 10 Gm. of monohydrated sodium carbonate (see page 1023) in sufficient distilled water to measure 100 mils.

Sodium Chloride, NaCl.—In addition to the requirements and tests prescribed for this salt under *Sodii Chloridum* (see page 1024), it is required to conform to the following more rigorous tests before it can be used in the preparation of tenth-normal sodium chloride V.S. To a solution of 3 Gm. of sodium chloride in 80 mils of distilled water, add 1 mil of concentrated hydrochloric acid (see page 1682), heat it to boiling, and add about 5 mils of barium chloride T.S.; no precipitation of barium sulphate takes place within twenty-four hours (*sulphate*). To a solution of 3 Gm. of sodium chloride in about 10 mils of distilled water, add 5 mils of ammonia water and 5 mils of sodium phosphate T.S.; no precipitation takes place within twelve hours (*magnesium salts*). Dissolve 5 Gm. of the salt in 80 mils of distilled water, heat the solution to boiling, and add 5 mils of ammonium oxalate T.S.; no precipitate is produced within twelve hours (*calcium*); nor is this solution affected by the addition of sodium carbonate T.S.; nor is a freshly prepared solution of the same concentration affected by the addition of sodium sulphide T.S. (*alkali earths and heavy metals*). To a solution of 1 Gm. of sodium chloride in 10 mils of distilled water, add 5 mils of sodium cobaltic nitrite T.S.; no precipitation occurs after twenty-four hours (*potassium*). The addition of Nessler's Reagent (see page 1684) to a solution of 3 Gm. of sodium chloride produces no yellow coloration (*ammonium salts*).

Sodium Cobaltic Nitrite Test Solution.—Dissolve 4 Gm. of cobaltous chloride (see page 1680) and 10 Gm. of sodium nitrite (see page 1032) in about 50 mils of distilled water, add 2 mils of acetic acid (see page 13) and dilute with sufficient distilled water to measure 100 mils. A few drops of acetic acid should be added to the solution from time to time. The reagent must not be kept longer than three months. Should any precipitate form on standing, filter the solution.

Sodium Cyanide Test Solution.—Dissolve 1 Gm. of sodium cyanide (see page 1027) in sufficient distilled water to measure 10 mils. This solution must be freshly prepared when required.

Sodium Hydroxide Test Solution, NaOH.—Use the official solution of sodium hydroxide (see page 660).

Sodium Hypobromite Test Solution.—To a solution of 40 Gm. of sodium hydroxide (see page 1028) in about 150 mils of distilled water add 10 mils of bromine (see page 1678) and, after solution has taken place, add sufficient distilled water to measure 200 mils. This solution must be freshly prepared when required for use.

Sodium Nitroprusside, $Na_2Fe(NO)(CN)_5+2H_2O$.—Transparent, dark red rhombic crystals, soluble in about 2.5 parts of water. With soluble sulphides it gives an intense, violet coloration. Solutions of sodium nitroprusside must be freshly prepared when required for use.

Sodium Nitroprusside Test Solution.—Dissolve 1 part of sodium nitroprusside in 19 parts of distilled water immediately before using.

Sodium Oxalate, $Na_2C_2O_4$.—A white crystalline powder, 1 Gm. of which dissolves in about 34 mils of water at 25°C. (77° F.), and about 16 mils of boiling water. When used for the standardization of tenth-normal potassium permanganate V.S., sodium oxalate should comply with the following tests for purity and be dried to constant weight at 105° C. (221° F.). When dried to constant weight at 105° C. (221° F.) sodium oxalate loses not more than 0.03 per cent. in weight (*moisture*). Introduce into a conical Jena or other flask of like quality 2 Gm. of sodium oxalate, add 150 mils of distilled water and 0.2 mil of phenolphthalein T.S., boil until the volume is reduced to about 100 mils, then cool while passing a current of air free from carbon dioxide through the solution. If the solution is red, not more than 0.2 mil of fiftieth-normal sulphuric acid V.S. is required to render it colorless. If the solution is colorless, not more than 0.2 mil of fiftieth-normal potassium hydroxide V.S. is required to produce a pink color. Sodium oxalate yields an almost perfectly clear solution and contains not more than 0.01 per cent. of matter insoluble in water. Convert 10 Gm. of the salt into carbonate by ignition in a platinum crucible using an alcohol burner, dissolve the residue in distilled water by the aid of sufficient nitric acid to impart a distinctly acid reaction, heat to boiling, filter and divide into two parts. To one part, add barium nitrate T.S. and set aside for twelve hours; not more than a barely perceptible cloudiness results (*sulphate*). The remaining portion, after the addition of silver nitrate T.S., does not yield more than a faint opalescence (*chloride*). Ignite 5 Gm. of the salt to carbonate, dissolve the residue in distilled water, acidify with acetic acid and filter; after the addition of a few drops of sodium cobaltic nitrite T.S. to the filtrate it should not yield more than a faint trace of precipitate after standing for several hours (*potassium*). Ignite 5 Gm. of the salt, dissolve the residue in distilled water acidify with hydrochloric acid and filter; the filtrate does not yield a coloration upon the addition of potassium sulphocyanate T.S. (*iron*). Heat 1 Gm. of the salt in a test tube, which has previously been rinsed with sulphuric acid, with 10 mils of sulphuric acid until fumes of sulphur trioxide appear; no discoloration of the acid is produced (*foreign organic bodies*).

Sodium Phosphate Test Solution.—Dissolve 10 Gm. of sodium phosphate, in clear crystals (see page 1035), in sufficient distilled water to measure 100 mils.

Sodium Phospho-tungstate Test Solution (Sodium Phospho-wolframate).—To a solution of 20 Gm. of sodium tungstate in 100 mils of water, add sufficient phosphoric acid (see page 54) to impart a strong acid reaction, filter and preserve it in an amber-colored, glass-stoppered bottle. Decant the solution from any sediment which may form.

Sodium Sulphide, Na_2S+9H_2O.—Colorless, or nearly colorless, transparent crystals, of sulphuretted odor, readily soluble in water, yielding a clear solution which is alkaline to litmus.

Sodium Sulphide Test Solution.—Dissolve 10 Gm. of sodium sulphide in sufficient distilled water to measure 100 mils; filter the solution if necessary. Sodium sulphide T.S. may be used in all instances where ammonium sulphide T.S. is directed, but must be freshly prepared when required for use.

Sodium Tartrate, Neutral, $Na_2C_4H_4O_6+2H_2O$.—Transparent crystals soluble in 2.6 parts of water at 25° C. (77° F.); insoluble in alcohol. It complies with the standards for purity required under *Potassii et Sodii Tartras* (see page 898); each mil of half-normal sulphuric acid V.S. corresponds to 0.057515 Gm. of $Na_2C_4H_4O_6+2H_2O$.

Sodium Tartrate Test Solution.—Dissolve 10 Gm. of neutral sodium tartrate (see above) in sufficient distilled water to measure 100 mils. Alternative method: To a hot solution of 6.5 Gm. of tartaric acid (see

page 78) in about 80 mils of boiling distilled water, add gradually, in small portions, monohydrated sodium carbonate (see page 1023) until the solution has a neutral reaction to litmus paper; after filtering and cooling add sufficient distilled water to measure 100 mils.

Sodium Thiosulphate, $Na_2S_2O_3+5H_2O$.—In addition to the tests prescribed for this salt under *Sodii Thiosulphas* (see page 1043) it is required to conform to the following more rigorous tests before it can be used in preparing the standard volumetric solution. Add iodine T.S., drop by drop, to a solution of the salt (1 in 20) in distilled water until it retains a faint but permanent yellow color; no turbidity is produced upon the addition of barium chloride T.S. (*sulphate and sulphite*). The addition of phenolphthalein T.S. to 10 mils of an aqueous solution of the salt (1 in 10) produces no pink coloration (*free alkalies*).

Sodium Thiosulphate Test Solution.—Use tenth-normal sodium thiosulphate V.S. (see page 1704).

Sodium Tungstate (Sodium Wolframate), $Na_2WO_4+2H_2O$.—Colorless prisms or plates, soluble in about 4 parts of Water, forming a solution which is alkaline to litmus. Evaporate a solution of 1 Gm. of sodium tungstate in 10 mils of distilled water and 10 mils of concentrated hydrochloric acid (see page 1682) to dryness on a water bath and then heat it for half an hour at 120° C. (248° F.). Treat the residue with 20 mils more of the hydrochloric acid, evaporate and heat as before, and repeat the operation three times. After cooling, digest the residue with a solution of ammonium nitrate (1 in 10) to which a few drops of nitric acid have been added, transfer it to a filter, wash the insoluble tungstic acid with diluted nitric acid, dry, ignite and weigh. (It is preferable to moisten this residue with a few drops of nitric acid and repeat the ignition.) This residue weighs not less than 0.69 Gm.

Stannous Chloride, $SnCl_2+2H_2O$.—Colorless crystals, readily soluble in water or alcohol. When in contact with the air or excess of water, the salt readily forms a basic chloride, hence, when dissolved, its solution should be acidulated with hydrochloric acid. When tested for arsenic as directed under the Test for arsenic (see Test No. 1), 0.3 Gm. of stannous chloride produces no stain. A solution of 2 Gm. of stannous chloride, in 1 mil of distilled water and 0.5 mil of hydrochloric acid, does not become opalescent on diluting with 20 mils of distilled water (*lead*). Alternative method: Heat tin (see page 1692) for several days with concentrated hydrochloric acid (see page 1682) upon a water bath, taking care that the metal is in excess. When the acid has become saturated, pour off the clear fluid from the undissolved tin or precipitate, filter it while still hot through asbestos and set it aside until crystallization takes place. Break up the crystals, drain, and dissolve them at once as directed under the Test Solution.

Stannous Chloride Test Solution.—Dissolve 1 Gm. of stannous chloride crystals (see above) in 10 mils of distilled water to which a few drops of hydrochloric acid have been added to prevent the precipitation of basic chloride, and preserve the solution in a glass-stoppered bottle in which a fragment of tin (see page 1692) has been placed. The solution must be renewed at frequent intervals.

Stannous Chloride Test Solution, Acid.—Dissolve 40 Gm. of stannous chloride crystals (see above) in 60 mils of concentrated hydrochloric acid (see page 1682) and preserve it in a glass-stoppered bottle.

Stannous Chloride Test Solution, Saturated.—(For Bettendorf's Arsenic Test, see Test No. 2.) Prepare a saturated solution of stannous chloride crystals (see above) in concentrated hydrochloric acid (see page 1682) or evaporate a solution prepared from metallic tin by the alternative method under *Stannous Chloride* (see above) to a specific gravity of about 2.00 at 25° C. (77° F.). After filtering the solution through asbestos it is transparent and has not more than a pale yellow color.

Starch (Potato).—The starch grains separated from the tubers of *Solanum tuberosum*, Linné (Fam. *Solanaceæ*). In a more or less finely granular powder, consisting of starch grains varying in shape from somewhat spherical or ellipsoidal to characteristic, with a few two- or three-compound grains; the individual grains with a circular point of origin of growth and distinct excentral lamellæ, the larger characteristic grains varying from 0.05 to 0.125 mm. in length, and under the micropolariscope showing a distinct cross and a strong play of color when a selenite plate is used.

Starch Test Solution.—Triturate 1 Gm. of corn starch (see page 142) with 10 mils of cold distilled water, add sufficient boiling distilled water with constant stirring to make about 200 mils, then boil the mixture for a few minutes until a thin, translucent fluid is obtained. This solution must be freshly prepared and filtered when required.

Succinic Acid, $H_2C_4H_4O_4$.—An organic acid obtained through the destructive distillation of amber or made synthetically. It forms colorless monoclinic prisms, soluble in about 20 parts of water, 2 parts of boiling water, 10 parts of alcohol, or 18 parts of acetone; very slightly soluble in ether and insoluble in chloroform or benzene. Succinic acid melts at about 182° C. (359.6° F.).

Sulphanilic Acid (Para-amidobenzenesulphonic Acid), $C_6H_4(NH_2)(SO_3H)1:4+2H_2O$.—Colorless, acicular, efflorescent crystals. When strongly heated, it carbonizes. Soluble in about 150 parts of cold water and insoluble in alcohol or ether.

Sulphanilic Acid Test Solution.—Dissolve 0.5 Gm. of sulphanilic acid in a mixture of 15 mils of glacial acetic acid and 135 mils of freshly distilled or recently-boiled distilled water. This reagent must be kept in well-stoppered bottles.

Sulpho-Salicylic Acid, $C_6H_3(OH)(SO_3H).COOH$.—Colorless, anhydrous needles very soluble in water and alcohol. It melts at about 120° C. (248° F.).

Sulphuric Acid.—Sulphuric acid of the purity required by the Pharmacopœia (see page 64), with a specific gravity of 1.832 at 25° C. (77° F.), will be satisfactory as a reagent unless otherwise directed.

Sulphuric Acid, Fuming, $H_2SO_4+SO_3$.—A heavy, fuming, oily liquid, sometimes slightly colored, containing from 14 to 16 per cent. of free sulphur trioxide corresponding to from 84.2 to 84.6 per cent. of total sulphuric anhydride, with a specific gravity of from 1.869 to 1.875 at 25° C. (77° F.). Great caution should be exercised in handling fuming sulphuric acid. Render the acid homogeneous by shaking vigorously, then transfer several mils to a glass-stoppered weighing flask and weigh accurately. Remove about 1 mil of the acid to a dish containing from 30 to 40 mils of distilled water and again accurately weigh the flask, thus noting the quantity of acid taken for the assay. Titrate the solution of the acid in the dish with normal potassium hydroxide V.S., using methyl orange T.S. as indicator. One mil of normal potassium hydroxide V.S. corresponds to 0.040035 Gm. of sulphuric anhydride (SO_3). The percentage of SO_3 thus found, when subtracted from 100, represents the water present, for each 18.02 parts of which, 80.07 parts of SO_3

are required for the formation of H_2SO_4. After allowing for all of the water in this manner, the remaining SO_3 may be termed free SO_3.

Sulphuric Acid, Purified and Concentrated, for Tests, H_2SO_4.—When concentrated sulphuric acid is specified in a test, it is intended that the strongest purified acid of a specific gravity of not less than 1.834 at 25° C. (77° F.), be employed. In addition to the tests prescribed for this acid under *Acidum Sulphuricum* (see page 67), it is required to conform to the following more rigorous tests before it can be employed as a reagent: Dilute 1 part of the acid with 4 parts of distilled water; no stain is produced by 25 mils of this diluted acid when subjected to the Test for arsenic (see Test No. 1). Dilute 1 mil of the acid with 9 mils of distilled water, cool and pour it so as to form a layer over 5 mils of diphenylamine T.S. (see page 1680); no blue color appears at the zone of contact (*nitric acid*). Upon carefully pouring about 2 mils of hydrochloric acid, in which a particle of sodium sulphite has been dissolved, over about 2 mils of the concentrated sulphuric acid, no reddish zone appears and no precipitate forms (*selenium*).

Sulphurous Acid.—An aqueous solution containing not less than 6 per cent. of sulphur dioxide. Ten mils of this solution, when mixed with 10 mils of dilute sulphuric acid (see under Arsenic Test, page 1709) and evaporated on a water bath until free from sulphur dioxide, does not produce a stain when subjected to the Test for arsenic (see Test No. 1). Introduce about 2 mils of the acid into a flask containing 10 mils of distilled water, previously tared with its contents, stopper and weigh accurately. To this add 50 mils of tenth-normal iodine V.S., allow to stand five minutes, then titrate the excess of iodine with tenth-normal sodium thiosulphate V.S. It shows not less than 6 per cent. of SO_2. Each mil of tenth-normal iodine V.S. corresponds to 0.003204 Gm. of SO_2.

Tannic Acid Test Solution.—Dissolve 1 Gm. of tannic acid (see page 75) in 1 mil of alcohol, and add sufficient distilled water to measure 10 mils. This test solution should be freshly prepared when needed.

Tartaric Acid Test Solution.—Dissolve 1 part of tartaric acid (see page 78) in 3 parts of distilled water. This solution must be frequently renewed.

Tin, Sn.—Metallic tin in the granulated or mossy condition. Digest 5 Gm. of tin with 40 mils or a sufficient quantity of nitric acid (see page 45) on a bath of boiling water until entirely converted into a white powder, then evaporate it to dryness. Stir the residue with 25 mils of diluted nitric acid (see page 50) and 25 mils of distilled water, and filter. To the filtrate add 1 mil of diluted sulphuric acid and evaporate it as far as possible upon a water bath, and then add 10 mils of distilled water; no weighable residue remains undissolved (*lead*). When converted into stannous chloride (see page 1691), it complies with the tests directed under that salt.

Toluol (Toluene, Methyl Benzene), $C_6H_5.CH_3$.—A colorless, refractive, inflammable liquid of peculiar aromatic odor; specific gravity about 0.865 at 25° C. (77° F.), boiling between 110° and 112° C. (230° and 233.6° F.). Miscible with alcohol, ether, chloroform, carbon disulphide, or petroleum benzin. It dissolves phosphorus, iodine, fats, or oils.

Trinitrophenol Test Solution (Picric Acid Test Solution), $C_6H_2(NO_2)_3.OH$.—Dissolve 1 Gm. of trinitrophenol (see page 1164) in 100 mils of distilled water by the aid of heat. Cool the solution and filter it if necessary.

Turmeric Paper and Tincture.—See under *Indicators* (page 1709).

Xylol (Xylene, Dimethyl Benzene), $C_6H_4(CH_3)_2$.—A mixture of ortho-, meta-, and para-xylene obtained through the distillation of coal tar naphtha. A colorless liquid of an odor resembling benzene. It boils between 136° and 140° C. (276.8° and 284° F.) specific gravity about 0.850 at 25° C. (77° F.); insoluble in water, but soluble in alcohol, ether, or chloroform.

Yeast.—Use the commercial compressed yeast cake.

Zinc, Zn.—Pure metallic zinc (see page 1216).

Zinc for the Arsenic Test.—Zinc in mossy or globular form, the latter about 3 to 6 mm. in diameter, known as No. 7 Shot Zinc. This must conform with the tests for purity as given under *Zincum* and in addition the following: The stain from 8 Gm. of zinc, when determined by a blank experiment as directed under the Test for arsenic (see Test No. 1), should scarcely be perceptible. Introduce 10 Gm. of the zinc into a flask of about 250 mils capacity, proved with a perforated rubber stopper and a rubber-valve tube, and containing 60 mils of distilled water, 15 mils of concentrated sulphuric acid for tests (see above) and 1 drop of copper sulphate T.S. When the reaction slackens, place the flask on a water bath and warm until solution of the zinc is complete. At once begin to add tenth-normal potassium permanganate V.S., drop by drop, with agitation, until the solution assumes a faint pink tint which remains permanent for one-half minute. Not more than 1.4 mils of tenth-normal potassium permanganate V.S. is required, indicating not over 0.08 per cent. of oxidizable matter, calculated as metallic iron (Fe).

Zinc Dust (Powdered Zinc).—Zinc in the form of a fine gray powder.

Zinc Oxide, ZnO.—When used in the assay of phosphoric acid, the phosphates or the hypophosphites, it must comply with the tests given under *Zinci Oxidum* (see page 1211) and also the following: Dissolve 1 Gm. of zinc oxide in 20 mils of distilled water and 5 mils of nitric acid in a test tube about 2 cm. in diameter and add a few drops of silver nitrate T.S.; not more than a slight opalescence is produced.

Volumetric Solutions

(U. S. P. IX)

It is absolutely necessary that the measuring vessels employed in the operations of volumetric analysis, consisting of burettes, flasks, mixing cylinders, pipettes, etc., shall agree among themselves accurately in their graduation at the standard temperature selected. All volumetric solutions should be prepared at the standard temperature of 25° C. (77° F.) and used in titrations, if practicable, at that standard temperature. If titrations are made at any other temperature, a volumetric solution should be used which has been standardized for such temperature. In case graduated apparatus calibrated at 25° C. (77° F.) is not procurable volumetric solutions may be prepared at the temperature for which the apparatus in hand was graduated (*e.g.*, 15° C. (59° F.) or 20° C. (68° F.)), and all such volumetric solutions should be marked to indicate the

temperature which has been used. Such solutions must be used as above stated at such standard temperature, care being taken that all graduated apparatus used be standardized at the same temperature.

Units of Capacity.—The units of volume employed by the Pharmacopœia must accord with its standard liter at 25° C. (77° F.) which represents the volume occupied by 996.04 Gm. of distilled water, weighed in air with brass weights, at a temperature of 25° C.[1] (77° F.) and barometer at 760 mm. To secure uniformity among the various forms of apparatus employed, the standard specifications of the U. S. Bureau of Standards should be adhered to as closely as possible, excepting that the temperature here adopted is 25° C. (77° F.). The tables for calibrating graduated apparatus will be found on page 1790.

Measuring Flasks.—Standard measuring flasks are calibrated to contain, when filled to the mark, 1000, 500, 250, 200 or 100 mils at 25° C. (77° F.). The necks must be of uniform calibre, and measure in diameter not less than 14 mm. nor more than 20 mm. for 1000 mil capacity; from 12 mm. to 18 mm. for 500 mil capacity; from 10 mm. to 15 mm. for 250 mil capacity and from 8 mm. to 12 mm. for 100 mil capacity. The capacity mark on any of these flasks should not be less than 6 cm. distant from the mouth and not less than 2 cm. from the base of the neck.

Cylinders.—These should be graduated to contain their respective volumes at the standard temperature. Their inside diameter must not be more than one-fifth the graduated length.

Transfer Pipettes.—These should be graduated to deliver at standard temperature the exact volume of fluid indicated. The suction stem should be at least 16 cm. long, and the delivery tube not less than 3 cm. nor more than 25 cm. long. The inside diameter at the capacity mark must not be less than 2 mm. and not exceed 4 mm. for those of 25 mil capacity. The capacity mark should not be more than 6 cm. from the bulb. The outlet of any transfer pipette should be of such size that the free outflow shall last not more than 1 minute, nor less than 15 seconds for 5 mils, 20 seconds for 10 mils and 30 seconds for 50 mils. After filling, the fluid adhering to the outside should be wiped from the stem; then when draining the contents, the pipette should be held in a vertical position; finally, to complete the emptying, the tip of the pipette should be held against the side of the vessel, permitting the last portions of the fluid to flow out by gravity. Pipettes should never be drained by blowing into them.

Burettes.—These must be provided with glass stop-cocks and be graduated for use at the standard temperature. Burettes provided with rubber tubes and pinch-cocks in place of glass stop-cocks may be used for potassium and sodium hydroxide V.S. The tips should be gradually tapered from 2 to 3 cm. in length and slightly bent. The rate of outflow should be regulated so that not less than 2 seconds should be consumed for each mil of the length of the column delivered. When completing titration, the tip of the delivery tube should be touched with the wet surface of the receiving vessel to complete the emptying.

General Directions.—All bottles in which volumetric solutions are to be kept, as well as the burettes or pipettes in which they are to be measured, should, prior to use, be thoroughly cleaned and rinsed first with distilled water, and then with two or three small portions of the solution that they are to contain. In all apparatus where the surface of the fluid is limited by a meniscus, the reading must be made from the lowest point of the meniscus unless the liquid is too opaque to permit exact observation of that point. It is of the utmost importance that the inner surface of all measuring apparatus shall be free from any suggestion of greasiness.

Normal volumetric solutions $\left(\frac{N}{1}\right)$ are those which contain in 1000 mils, in any stated reaction, the chemical equivalent of one gramme of hydrogen. If the molecule of the reagent is univalent, one liter will contain a weight in grammes equal to the molecular weight of the reagent; if bivalent, a weight in grammes equal to one-half its molecular weight; if trivalent, a weight in grammes equal to one-third its molecular weight. Thus, hydrochloric acid, HCl = 36.47, having but one H atom replaceable by a basic element, has 36.47 Gm. of HCl in 1000 mils of the normal volumetric solution; while sulphuric acid, $H_2SO_4 = 98.09$, having two replaceable H atoms, contains only one-half this number, or 49.045 Gm. of H_2SO_4 in 1000 mils of its normal solution. Potassium hydroxide, KOH = 56.11, has but one K to replace one H in acids, hence its normal solution contains 56.11 Gm. of KOH in one liter. Again, one molecule of potassium dichromate ($K_2Cr_2O_7 = 294.20$) in oxidation liberates three atoms of oxygen which are capable of oxidizing six atoms of ferrous to ferric iron. Therefore, each molecule of the dichromate, yielding three atoms of oxygen, is equivalent to six atoms of hydrogen. Hence, the normal solution should contain $\frac{294.20}{6}$ or 49.0333 Gm. in 1000 mils. Two molecules of potassium permanganate, $2KMnO_4 = 316.06$, in oxidation, give off five atoms of O, which are equivalent to ten atoms of H; hence its normal solution should contain $\frac{316.06}{10}$ or 31.606 in 1000 mils. Solutions containing in 1000 mils one-tenth of the quantity of the active reagent in the normal solution are called tenth-normal $\left(\frac{N}{10}\right)$ (normality = 0.1); those containing one-hundredth, hundredth-normal $\left(\frac{N}{100}\right)$ (normality = 0.01) those containing one-fiftieth, fiftieth-normal $\left(\frac{N}{50}\right)$ (normality = 0.02); those containing twice the amount, double-normal $\left(\frac{2N}{1}\right)$ (normality = 2); half the amount, half-normal $\left(\frac{N}{2}\right)$ (normality = 0.5). Solutions containing quantities of the active reagent having no simple relation to the molecular weight are called empirical.

Use of Empirical Solutions.—All standard volumetric solutions are liable to deteriorate in time, some very slowly, others rapidly, especially when not properly preserved. To restore the titer of such solutions (that is, to make them exactly normal, tenth-, or hundredth-normal, as the case may be) each time they are to be used, involves an unnecessary waste of time. If one accurately standardized solution be always available, it is not necessary that the other volumetric solutions employed in conjunction with it be adjusted to exactly correspond, mil for mil, so long as the *exact* ratio is known at standard temperature. The percentage strength of any empirical solution as compared with a standard volumetric solution is ascertained by experiment, then the number of mils of the empirical solution consumed in the titration of the substance is multiplied by its percentage strength, which product represents the equivalent volume of the true standard solution.

[1] 500 mils would weigh 498.02 Gm.; 250 mils, 249.01 Gm.; 100 mils, 99.604 Gm.

Example: One gramme of potassium carbonate required for neutralization 22 mils of an empirical solution of hydrochloric acid. In a trial experiment, 16 mils of this weak solution was required to neutralize 10 mils of a standard normal potassium hydroxide V.S. The former was therefore of 62.5 per cent. strength (for 16 : 10 : : 100 : x. $x = 62.5$), hence the 22 mils of empirical solution consumed represents 13.75 mils (62.5 per cent. of 22) of standard normal hydrochloric acid V.S. Therefore since 1 mil of $\frac{N}{1}$ hydrochloric acid V.S. = 0.0691 Gm. of K_2CO_3, 13.75 mils would be equivalent to 13.75×0.0691 or 0.9501 + Gm. of potassium carbonate.

Adjustment of titer of volumetric solutions which are above strength. Titrate 25 mils of the strong solution, with a carefully standardized corresponding solution, which must be of the same standard temperature. The number of mils of the latter consumed, divided by 25, will give the factor to be employed in adjusting the strength of the former.

Example: 25 mils of a " strong " normal solution of hydrochloric acid required 27.25 mils of standard normal potassium hydroxide V.S. for neutralization. The correcting factor is therefore $27.25 \div 25 = 1.09$. If the " strong " solution measures 875 mils its volume must be made up with distilled water to $875 \times 1.09 = 953.75$ mils. Add therefore to the " strong " solution $953.75 - 875 = 78.75$ mils of distilled water. After the solution is thus diluted, its titer should be verified by the titration of 25 mils with the standard normal potassium hydroxide V.S., the measurements in each case being made at 25° C. (77° F.) (or at least at the same temperature). It should require exactly 25 mils of the latter for neutralization. If this is not the case, either a new adjustment must be made, or else the new correction factor must be plainly written on the label of the bottle, and the required correction made whenever the solution is used.

Alkaline Cupric Tartrate Volumetric Solution

[Fehling's Solution]

A. The Copper Solution.—Dissolve 34.66 Gm. of carefully selected, small crystals of cupric sulphate (*Cupri Sulphas*, U.S.P.), showing no trace of efflorescence or of adhering moisture, in a sufficient quantity of distilled water to make the solution measure exactly 500 mils at standard temperature. Keep this solution in small, well-stoppered bottles.

B. The Alkaline Tartrate Solution.—Dissolve 173 Gm. of crystallized potassium and sodium tartrate (*Potassii et Sodii Tartras*, U.S.P.) and 50 Gm. of sodium hydroxide (*Sodii Hydroxidum*, U.S.P.) in a sufficient quantity of distilled water to make the solution measure exactly 500 mils at standard temperature. Keep the solution in small, rubber-stoppered bottles. For use, mix exactly equal volumes of the two solutions at the time required.[1]

One Mil of the Mixed Solution is the equivalent of:

	Gramme.
Cupric Sulphate, crystallized, $CuSO_4 + 5H_2O$	0.03466
Cupric Tartrate, $CuC_4H_4O_6 + 3H_2O$	0.03688
Cane Sugar, $C_{12}H_{22}O_{11}$ (after inversion)	0.00475
Glucose, anhydrous, $C_6H_{12}O_6$	0.00500
Milk Sugar, anhydrous, $C_{12}H_{22}O_{11}$	0.00678

Tenth-Normal Barium Hydroxide Volumetric Solution

$Ba(OH)_2 + 8H_2O = 315.51$ 15.776 Gm. in 1000 mils

Dissolve about 18 Gm. of crystallized barium hydroxide in 1000 mils of recently boiled and cooled distilled water, and, if necessary, filter the solution quickly.

Introduce 25 mils of tenth-normal sulphuric acid V.S. or preferably tenth-normal hydrochloric acid V.S. into a flask, add 3 drops of phenolphthalein T.S., and run in the barium hydroxide solution from a burette, provided with a soda-lime tube, reducing the flow to drops towards the end, until a pale pink color is produced which no longer disappears on shaking the liquid for about ten seconds. Note the number of mils of the barium hydroxide solution consumed, and, if the solution is too concentrated, dilute the remainder of the solution with freshly boiled and cooled distilled water, so that equal volumes of the barium hydroxide solution and of tenth-normal sulphuric or hydrochloric acid at 25° C. (77° F.) exactly neutralize each other.

Note.—This solution absorbs carbon dioxide from the air very rapidly, thereby changing its titer. It should, therefore, be preserved in rubber-stoppered bottles provided with a soda-lime tube (see under normal potassium hydroxide V.S.). This solution must also be standardized each time before using.

One Mil of Tenth-Normal Barium Hydroxide V.S. is the equivalent of:

	Gramme.
Barium Hydroxide, $Ba(OH)_2 + 8H_2O$	0.015776
Ammonium Benzoate, $NH_4C_7H_5O_2$	0.013908
Ammonium Salicylate, $NH_4C_7H_5O_3$	0.015508
Benzoic Acid, $C_7H_6O_2$	0.012205
Hydrochloric Acid, HCl	0.003647
Salicylic Acid, $C_7H_6O_3$	0.013805
Sulphuric Acid, H_2SO_4	0.0049045

[1] The accuracy of this solution when employed in titration may be verified as follows: To a solution of 0.95 Gm. of pure cane sugar in about 50 mils of distilled water, add 2 mils of hydrochloric acid and heat at 70° C. (158° F.) for ten minutes. After neutralizing with sodium carbonate, dilute the solution to 1000 mils. Fifty mils of this dilution should reduce the copper in exactly 10 mils of the solution.

Tenth-Normal Bromine Volumetric Solution

[KOPPESCHAAR'S SOLUTION]

Br = 79.92. 7.992 Gm. in 1000 mils.

Dissolve 3 Gm. of potassium bromate (see page 1687) and 50 Gm. of potassium bromide in sufficient distilled water to measure 1000 mils at or near 25° C. (77° F.). Transfer 20 mils of this solution at standard temperature, by means of a pipette, to a bottle having a capacity of about 250 mils, and provided with a glass stopper; add 75 mils of distilled water and 5 mils of hydrochloric acid (see page 33) and immediately insert the stopper. Shake the bottle a few times, then remove the stopper just sufficiently to quickly introduce 5 mils of potassium iodide T.S., taking care that no bromine vapors escape, and immediately stopper the bottle. Agitate the bottle thoroughly, remove the stopper and rinse it and the neck of the bottle with a little distilled water so that the washings flow into the bottle, and then add from a burette tenth-normal sodium thiosulphate V.S. until the solution is only slightly yellow, then add a few drops of starch T.S. and continue the addition of the tenth-normal sodium thiosulphate V.S. until the blue color is just discharged. Note the number of mils of the sodium thiosulphate V.S. thus consumed, and then dilute the bromine solution so that equal volumes of it and of tenth-normal sodium thiosulphate V.S. will exactly correspond to each other under the conditions mentioned above. Keep the solution in dark amber-colored, glass-stoppered bottles.

EXAMPLE: Assuming that the 20 mils of the bromine solution have required 22.5 mils of the sodium thiosulphate V.S. to completely discharge the iodine tint, then each 20 mils of the bromine solution must be diluted to 22.5 mils. Thus, if 960 mils of the solution remain, it must be diluted with distilled water to measure 1080 mils. After the solution is thus diluted, a new trial should be made in the manner above described, in which 25 mils of the tenth-normal sodium thiosulphate V.S. should just discharge the tint of the iodine liberated by the bromine set free from 25 mils of the standard bromine solution.

One Mil of Tenth-Normal Bromine V.S. is the equivalent of:

	Gramme.
Bromine, Br	0.007992
Orcin, $C_7H_6(OH)_2$	0.002068
Phenol, C_6H_5OH	0.001568
Resorcinol, $C_6H_4(OH)_2$	0.001834
Sodium Phenolsulphonate, anhydrous, $NaC_6H_5O_4S$	0.004903
Sodium Phenolsulphonate, crystallized, $NaC_6H_5O_4S+2H_2O$	0.0058035

Normal Hydrochloric Acid Volumetric Solution

HCl = 36.47. 36.47 Gm. in 1000 mils.

Mix 110 mils of hydrochloric acid (*Acidum Hydrochloricum*, U.S.P.) with sufficient distilled water to measure 1000 mils. Of this liquid (which is still too concentrated) carefully measure, at standard temperature from a burette, 25 mils into a flask or porcelain dish, and, after diluting with about double its volume of distilled water, add 2 drops of methyl orange T.S., then gradually add from a burette a freshly standardized normal potassium hydroxide V.S. at the same temperature, until the red or pink tint of the solution changes, after continuous shaking or stirring, to a permanent pale yellow. Note the number of mils of potassium hydroxide V.S. consumed, and then dilute the acid solution so that equal volumes of this and of the normal potassium hydroxide V.S. neutralize each other at 25° C. (77° F.).

EXAMPLE: Assuming that 25 mils of the acid solution first prepared required exactly 27.5 mils of normal potassium hydroxide V.S., each 25 mils of the former must be diluted to 27.5 mils or the whole of the remaining acid solution in the same proportion at standard temperature. Thus, if 950 mils should remain, 95 mils of distilled water must be added. After the liquid is thus diluted, a new trial should be made in the manner above described, in which 25 mils of the acid solution should require for neutralization exactly 25 mils of normal potassium hydroxide V.S. If necessary, a new adjustment should then be made to render the correspondence perfect at standard temperature.

ALTERNATIVE METHOD.—Normal hydrochloric acid V.S. may be standardized as directed under normal sulphuric acid V.S., employing the alternative method.

One Mil of Normal Hydrochloric Acid V.S. is the equivalent of:

	Gramme.
Hydrochloric Acid, HCl	0.03647
Barium Hydroxide, $Ba(OH)_2+8H_2O$	0.15776
Calcium Carbonate, $CaCO_3$	0.050035
Calcium Hydroxide, $Ca(OH)_2$	0.037045
Calcium Oxide, CaO	0.028035
Potassium Hydroxide, KOH	0.05611
Sodium Borate, anhydrous, $Na_2B_4O_7$	0.1010
Sodium Borate, crystallized, $Na_2B_4O_7+10H_2O$	0.19108
Sodium Cacodylate, anhydrous, $Na(CH_3)_2.AsO_2$	0.1600
Sodium Hydroxide, NaOH	0.04001

NOTE: Normal hydrochloric acid is in every respect equivalent in neutralizing power to normal sulphuric acid (see page 1704), and may be employed, except in special cases, for the same purposes.

Half-Normal Hydrochloric Acid Volumetric Solution

HCl = 36.47. 18.235 Gm. in 1000 mils.

Dilute 500 mils of normal hydrochloric acid V.S. at 25° C. (77° F.) with sufficient distilled water to measure at the same temperature exactly 1000 mils.

One Mil of Half-Normal Hydrochloric Acid V.S. is the equivalent of:

Tenth-Normal Iodine Volumetric Solution

I = 126.92. 12.692 Gm. in 1000 mils.

Tenth-normal iodine V.S. may be prepared according to either of the following methods:

I. Dissolve 12.692 Gm. of purified iodine (see page 1683) in a solution of 18 Gm. of potassium iodide in 300 mils of distilled water. Then add sufficient distilled water to make the solution measure exactly 1000 mils at standard temperature. Transfer the solution to glass-stoppered bottles. Unless freshly prepared, its strength should always be determined anew at the time it is used.

II. Tenth-normal iodine V.S. may also be prepared as follows:

Dissolve about 14 Gm. of iodine (*Iodum*, U.S.P.) in a solution of 18 Gm. of potassium iodide (*Potassii Iodidum*, U.S.P.) in about 300 mils of distilled water, diluting finally to 1000 mils. Carefully measure from a burette 25 mils of this solution (which is too concentrated), into a flask, then add gradually and cautiously from a burette tenth-normal sodium thiosulphate V.S. (shaking constantly), until the color of the solution is but slightly yellow, then add a few drops of starch T.S. and continue the addition of the tenth-normal sodium thiosulphate V.S. until the blue color is just discharged. Note the number of mils of the sodium thiosulphate V.S. consumed, and then dilute the iodine solution so that 25 mils will require for decolorization exactly 25 mils of the tenth-normal sodium thiosulphate V.S. at standard temperature.

One Mil of Tenth-Normal Iodine V.S. is the equivalent of:

	Gramme.
Iodine, I	0.012692
Acetone, $(CH_3)_2CO$	0.0009675

Tenth-Normal Oxalic Acid Volumetric Solution

$H_2C_2O_4+2H_2O=126.05$. 6.3025 Gm. in 1000 mils.

Dissolve 6.45 Gm. of purified oxalic acid (see page 1686) in sufficient distilled water to measure 1000 mils. Into a flask accurately measure from a burette 25 mils of a freshly standardized tenth-normal potassium hydroxide V.S., dilute with about 20 mils of distilled water, add 3 to 5 drops of phenolphthalein T.S. and heat it to boiling. From a burette gradually add the oxalic acid solution (which is still too concentrated) until the red tint of the alkali solution fails to reappear after vigorous shaking and boiling. Note the number of mils of the oxalic acid solution consumed, and then dilute it so that equal volumes of this and of the tenth-normal potassium hydroxide V.S. neutralize each other at standard temperature. This volumetric solution deteriorates on standing, hence must be frequently renewed or restandardized.

NOTE: Tenth-normal oxalic acid V.S. is in every respect equivalent in neutralizing power to any other tenth-normal acid V.S. with either litmus or phenolphthalein T.S. as indicator. Its specific use, however, is in standardizing or determining an excess of tenth-normal potassium permanganate V.S.

One Mil of Tenth-Normal Oxalic Acid V.S. is the equivalent of:

	Gramme.
Oxalic Acid, crystallized, $H_2C_2O_4+2H_2O$	0.0063025

Potassium Permanganate, $KMnO_4$	0.0031606
Sodium Hydroxide, NaOH	0.004001

Tenth-Normal Potassium Dichromate Volumetric Solution

$K_2Cr_2O_7=294.20$. 4.9033 Gm. in 1000 mils.

Dissolve 4.9033 Gm. of purified potassium dichromate (see page 1687), which has been pulverized and dried to constant weight at 120° C. (248° F.), in sufficient distilled water to measure exactly 1000 mils at standard temperature. When used as an oxidizing agent in titration to convert ferrous into ferric salts, or to liberate iodine from potassium iodide, the solution just mentioned (containing 14.710 Gm. in 1000 mils) has the effect of a $\frac{3N}{10}$ volumetric solution, and a solution of one-third of this strength, containing 4.9033 Gm. in 1000 mils, has the value of a tenth-normal solution, and is the equivalent of an equal volume of tenth-normal potassium permanganate V.S., or, in the case of iodine liberated from potassium iodide, it is the equivalent of an equal volume of tenth-normal sodium thiosulphate V.S. For titrating iron in ferrous compounds, it is used in the following manner. Introduce the aqueous solution of the ferrous salt into a flask and, if it is not already acid, render it so with sulphuric acid. Now add gradually tenth-normal potassium dichromate V.S. from a burette with agitation until a drop taken out upon a white surface no longer becomes blue when mixed with a drop of freshly prepared potassium ferricyanide T.S. Tenth-normal potassium dichromate V.S. may also be used in conjunction with potassium iodide (from which it liberates iodine) and sulphuric acid, for adjusting the titer of sodium thiosulphate V.S., and thus that of the iodine V.S.

One Mil of Tenth-Normal Potassium Dichromate V.S. is the equivalent of:

	Gramme.
Potassium Dichromate, $K_2Cr_2O_7$	0.0049033
Ferrous Carbonate, $FeCO_3$	0.011584
Ferrous Sulphate, anhydrous, $FeSO_4$	0.015191
Ferrous Sulphate, crystallized, $FeSO_4+7H_2O$	0.027802
Iron, in ferrous compounds, Fe	0.005584
Sodium Thiosulphate, $Na_2S_2O_3+5H_2O$	0.024822

Normal Potassium Hydroxide Volumetric Solution

$KOH=56.11$. 56.11 Gm. in 1000 mils.

Dissolve 75 Gm. of potassium hydroxide (see page 899) in sufficient recently boiled distilled water to measure about 1050 mils and fill a burette with a portion of this liquid. Into a flask of the capacity of about 300 mils, introduce 4.7035 Gm. of potassium bitartrate (which has been purified and dried as directed on page 1687) followed by 15 mils (accurately measured at 25° C. (77° F.)) of the potassium hydroxide solution which is being prepared and 80 mils of distilled water. Heat the solution to boiling, add from 3 to 5 drops of phenolphthalein T.S. and then cautiously, at standard temperature from a burette, further portions of the potassium hydroxide solution. Agitate the flask frequently, boil the liquid toward the end of the operation and reduce the flow of potassium hydroxide solution to drops, until the red color produced by its influx no longer disappears on shaking, and the liquid is not deeper in color than a pale pink. Note the total number of mils of the potassium hydroxide solution consumed, and then dilute the remainder of the solution so that exactly 25 mils of the diluted liquid, at standard temperature. shall be required to neutralize 4.7035 Gm. of the purified and dried potassium bitartrate.

EXAMPLE: Assuming that 20 mils of the stronger solution of potassium hydroxide first prepared had been consumed in the trial, then each 20 mils must be diluted to 25 mils or the whole of the remaining solution in the same proportion at standard temperature. Thus, if 1000 mils should be still remaining, this must be diluted with water to 1250 mils. After the liquid is thus diluted, a new trial should be made in the manner above described, in which 25 mils of the diluted solution should exactly neutralize 4.7035 Gm. of potassium bitartrate at standard temperature. If necessary, a new adjustment should then be made to render the correspondence perfect.

ALTERNATIVE METHOD.—Normal potassium or sodium hydroxide V.S. may be standardized against normal sulphuric acid V.S. which has been standardized by its alternative method, employing the trial solution directed in the first paragraph. Measure accurately 25 mils of this solution, at standard temperature, from a burette into a flask, add 2 drops of methyl orange T.S. or methyl red T.S., and afterwards from a burette the standard normal sulphuric acid V.S. at the same temperature, shaking after each addition, and, toward the end of the operation, reducing the flow to drops, until the yellow tint of the solution changes to a permanent rose after shaking. Note the number of mils of normal sulphuric acid V.S. consumed. Then dilute the potassium hydroxide solution so that 25 mils of this and 25 mils of the normal sulphuric acid V.S., at standard temperature, exactly neutralize each other.

NOTE: Solutions of caustic alkalies absorb carbon dioxide from the atmosphere, and thereby change their titer when used with litmus T.S., or phenolphthalein T.S. (in cold solution), as indicator (methyl orange T.S. is not affected by the presence of carbonic acid). Hence the volumetric solutions should be preserved in bottles provided with well-fitting rubber stoppers, or, better still, these should be provided with the tubes filled with soda-lime (a mixture of caustic soda and lime); the tubes pass through a perforation in the rubber stoppers and thus absorb the carbon dioxide and prevent its access to the solution. If the solution is kept in a burette for more than a few minutes, the same provision with a soda-lime tube should be observed. In place of potassium hydroxide V.S., sodium hydroxide V.S. (see page 1703) may be used, in the same manner and in the same quantity.

Half-Normal Potassium Hydroxide Volumetric Solution

KOH = 56.11. 28.055 Gm. in 1000 mils.

Dilute 500 mils of freshly standardized normal potassium hydroxide V.S., at standard temperature, with sufficient recently boiled distilled water at the same temperature to measure exactly 1000 mils. This solution may also be prepared and standardized directly with potassium bitartrate, as directed under normal potassium hydroxide V.S., employing for this purpose 2.3518 Gm. of the former and a solution of about 35 Gm. of potassium hydroxide (*Potassii Hydroxidum*, U.S.P.) in 1000 mils of distilled water. Twenty-five mils of half-normal solution, at standard temperature, should exactly neutralize 2.3518 Gm. of potassium bitartrate (see page 1687). The solution may also be standardized by comparison with half-normal sulphuric acid V.S., employing methyl orange T.S. as indicator.

NOTE: The same precautions should be taken for protecting this solution from carbon dioxide of the air as are directed under normal potassium hydroxide V.S.

Tenth-Normal Potassium Hydroxide Volumetric Solution

KOH = 56.11. 5.611 Gm. in 1000 mils.

Dilute 100 mils of freshly standardized normal potassium hydroxide V.S., at standard temperature, with sufficient recently boiled distilled water at the same temperature to measure exactly 1000 mils. This solution may also be prepared and standardized directly with potassium bitartrate, as directed under normal potassium hydroxide V.S., employing for this purpose 0.9407 Gm. of the bitartrate and a solution of about 7.5 Gm. of potassium hydroxide (*Potassii Hydroxidum*, U.S.P.) in 1000 mils of distilled water. Fifty mils of tenth-normal solution, at standard temperature, should exactly neutralize 0.9407 Gm. of potassium bitartrate (see page 1687). This solution may also be standardized by comparison with tenth-normal sulphuric acid V.S., employing methyl orange T.S. as indicator.

NOTE: The same precautions should be taken for protecting this solution from carbon dioxide of the air as are directed under normal potassium hydroxide V.S.

One Mil of Tenth-Normal Potassium Hydroxide V.S. is the equivalent of:

	Gramme.
Potassium Hydroxide, KOH	0.005611
Betaeucaine Hydrochloride, $C_{15}H_{21}O_2N.HCl$	0.028365
Lactic Acid, $HC_3H_5O_3$	0.009005
Potassium Bitartrate, $KHC_4H_4O_6$	0.018814
Sulphuric Acid, H_2SO_4	0.0049045

Fiftieth-Normal Potassium Hydroxide Volumetric Solution

KOH = 56.11. 1.1222 Gm. in 1000 mils.

Dilute 20 mils of a freshly standardized normal or preferably 200 mils of tenth-normal potassium hydroxide V.S., at standard temperature, with sufficient recently boiled distilled water at the same temperature to measure exactly 1000 mils. Verify the titer of this solution by titrating 0.1881 Gm. of potassium bitartrate (see page 1687) which should require for neutralization exactly 50 mils of the volumetric solution. This standard solution is employed in conjunction with the tenth-normal sulphuric acid V.S. in the titration of alkaloids, with hematoxylin, cochineal, methyl red, or iodeosin T.S. as indicators. The relative value of these two volumetric solutions should be determined each time, using the indicator employed in the alkaloidal assay.

NOTE: The same precautions should be taken for protecting this solution from carbon dioxide of the air as are directed under normal potassium hydroxide V.S. It should be renewed at frequent intervals.

One Mil of Fiftieth-Normal Potassium Hydroxide V.S. is the equivalent of:

	Gramme.
Potassium Hydroxide, KOH	0.0011222
Potassium Bitartrate, $KHC_4H_4O_6$	0.0037628
Sulphuric Acid, H_2SO_4	0.0009809

Hundredth-Normal Potassium Hydroxide Volumetric Solution

KOH = 56.11. 0.5611 Gm. in 1000 mils.

Dilute 10 mils of normal or preferably 100 mils of tenth-normal potassium hydroxide V.S., at standard temperature, with sufficient recently boiled distilled water at the same temperature to measure exactly 1000 mils. Verify the titer of this solution by titrating 0.0941 Gm. of potassium bitartrate (see page 1687), which should require for neutralization exactly 50 mils of the volumetric solution at standard temperature. This solution must be frequently renewed.

One Mil of Hundredth-Normal Potassium Hydroxide V.S. is the equivalent of:

	Gramme.
Potassium Hydroxide, KOH	0.0005611
Potassium Bitartrate, $KHC_4H_4O_6$	0.0018814
Sulphuric Acid, H_2SO_4	0.00049045

Half-Normal Alcoholic Potassium Hydroxide Volumetric Solution

KOH = 56.11. 28.055 Gm. in 1000 mils.

Dissolve from 2 to 3 Gm. of silver nitrate in 5 mils of distilled water and add the solution to 1200 mils of alcohol (*Alcohol*, U.S.P.) in a glass-stoppered bottle, and mix thoroughly. Dissolve about 5 Gm. of potassium hydroxide (see page 899) in 25 mils of warm alcohol, cool the solution, and pour it slowly without stirring, into the alcoholic solution of silver nitrate. Let the mixture stand until the precipitated silver oxide has settled, filter and distil. Dissolve about 35 Gm. of potassium hydroxide (see page 899) in 20 mils of distilled water and add sufficient alcohol, purified as directed above, to measure 1000 mils. Let the solution stand in a glass-stoppered or rubber-stoppered bottle for one day, then quickly decant the clear, supernatant solution into a bottle provided with a well-fitted rubber stopper. Into a flask of the capacity of about 300 mils introduce 2.3518 Gm. of potassium bitartrate, which has been purified and dried, as directed on page 1687, and about 100 mils of distilled water. Heat the solution to the boiling point, add about 5 drops of phenolphthalein T.S., then run in cautiously at standard temperature from a burette the potassium hydroxide solution prepared as above, keeping the liquid hot and frequently agitating the flask, and, toward the end of the operation, reducing the flow to drops until the red color produced by its influx no longer disappears on shaking, and the liquid is not deeper than pale pink. Note the number of mils of the alcoholic potassium hydroxide solution consumed, and then dilute the remainder of the solution with alcohol purified as directed above, so that exactly 25 mils of the diluted liquid, at standard temperature, shall be required to neutralize 2.3518 Gm. of potassium bitartrate.

Half-normal alcoholic potassium hydroxide V.S. may also be standardized as follows: Of the above described concentrated alcoholic potassium hydroxide solution, carefully measure, at standard temperature, from a burette 30 mils into a flask, and, after diluting with about 50 mils of distilled water, add about 5 drops of phenolphthalein T.S., heat to boiling temperature, and add from a burette half-normal hydrochloric acid V.S., at standard temperature, frequently agitating the flask, and, toward the end of the operation, reducing the flow to drops until the red color of the liquid is just discharged. Note the number of mils of the half-normal hydrochloric acid V.S. consumed, and then dilute the remainder of the solution with the purified alcohol so that 25 mils of this and 25 mils of half-normal hydrochloric acid V.S., at standard temperature, neutralize each other. Should half-normal hydrochloric acid V.S. not be available, standardization can be carried out in the same manner with normal hydrochloric acid V.S., two volumes of the alcoholic potassium hydroxide being made to correspond with one volume of the normal acid.

NOTE: This solution should be kept in bottles provided with well-fitted rubber stoppers and protected from the light. Owing to the readiness with which this standard solution loses its titer blank tests should be performed whenever it is employed in titrations. It is important that this volumetric solution be standardized at the temperature at which it is used.

One Mil of Half-Normal Alcoholic Potassium Hydroxide V.S. is the equivalent of:

Tenth-Normal Potassium Permanganate Volumetric Solution

$KMnO_4$ = 158.03. 3.1606 Gm. in 1000 mils.

Introduce about 3.3 Gm. of crystallized potassium permanganate (*Potassii Permanganas*, U.S.P.) into a flask, add 1000 mils of distilled water, and boil for about five minutes. Close the flask with a plug of purified absorbent cotton, and set it aside for at least two days, so that suspended matter may deposit. After the lapse of this time, pour off the clear portion of the solution into a glass-stoppered bottle. The water to be employed for diluting this solution (which is still too concentrated) should be prepared as directed under distilled water (*Aqua Destillata*, U.S.P.), adding, however, about 1 Gm. of potassium permanganate to each liter of water in the retort before beginning the distillation.

The solution may be standardized as follows:

I. Introduce about 0.3 Gm. of sodium oxalate (see page 1690), previously dried to constant weight at 110° C. (230° F.) and accurately weighed, into a beaker of about 400 mils capacity. Dissolve the salt in 250 mils of distilled water, heated to 85° C. (185° F.) and add 5 mils of concentrated sulphuric acid (see page 1692) diluted with an equal volume of distilled water. To this solution, kept at 85° C. (185° F.), add, from a burette, the permanganate solution to be standardized, stirring vigorously and continually with a thermometer, the solution being added not faster than at the rate of from 10 to 15 mils per minute. The last 0.5 to 1 mil of the solution required must be added, drop by drop, with particular care to see that each drop is fully decolorized before introducing the next. When the solution has assumed a faintly pink tint (remaining permanent for thirty seconds), the titration should cease. The excess of permanganate solution required to cause an end-point color must be estimated by matching the color of the liquid being tested with a measured quantity of the same permanganate solution in another beaker containing the same volumes of hot distilled water and sulphuric acid. Note the number of mils of the permanganate solution consumed in the trial titration and deduct from this volume the amount of permanganate solution required to produce the same tint in the water and acid mixture; the difference represents the number of mils of the permanganate solution required to reach the exact end-point in the trial titration.

Each 0.0067 Gm. of sodium oxalate is equivalent to 1 mil of tenth-normal potassium permanganate V.S. The number of grammes of sodium oxalate taken, when multiplied by 149.2537, indicates the number of mils of tenth-normal potassium permanganate V.S. required. The solution may now be adjusted to exactly tenth-normal strength or the factor may be determined and the solution employed empirically. In the former instance note the number of mils of the trial permanganate solution consumed, then dilute it so that the volume of diluted solution corresponds to that obtained by calculation from the sodium oxalate taken.

EXAMPLE: Assuming that 0.25 Gm. of sodium oxalate was taken, and 35.2 mils of the trial potassium permanganate solution was consumed. Then $0.25 \times 149.2537 = 37.313$, and therefore 35.2 mils (or 352 mils) of the trial potassium permanganate solution are diluted to 37.3 mils (or 373.13 mils). The factor of this trial solution for use as an empirical solution may be determined by dividing the number of mils of the trial permanganate solution consumed, by the number of mils representing the true equivalent volume (product of 149.2537 × the grammes of sodium oxalate used). $37.313 \div 35.2 = 106.00$, which is the percentage strength of the solution based upon the true tenth-normal V.S.

II. Tenth-normal potassium permanganate V.S. may also be standardized as follows:

To a solution of about 1 Gm. of potassium iodide (*Potassii Iodidum*, U.S.P.) in 10 mils of diluted sulphuric acid contained in a flask, slowly add from a burette 25 mils of the potassium permanganate solution to be standardized; mix well, then dilute the mixture at once with about 200 mils of distilled water. Add slowly an accurately standardized tenth-normal sodium thiosulphate V.S. from a burette, shaking the mixture vigorously, until the liquid is but slightly yellow, then add a few drops of starch T.S. and continue the addition of the tenth-normal sodium thiosulphate V.S. until the blue color is just discharged. Note the number of mils of the latter consumed, then dilute the permanganate solution so that 25 mils of the solution corresponds to 25 mils of the tenth-normal sodium thiosulphate V.S. under the same conditions at standard temperature. At least three careful titrations should be made, accepting the average, before diluting.

EXAMPLE: Assuming that 25 mils of the tenth-normal sodium thiosulphate V.S. was required to decolorize the iodine liberated by 20 mils of the permanganate solution, then each 20 mils of the potassium permanganate solution remaining must be diluted with the specially prepared distilled water to 25 mils, or the whole of the remaining solution in the same proportion. Thus, if 920 mils remain, it should be diluted, at standard temperature, to measure 1150 mils. After the potassium permanganate solution is thus diluted, a new trial should be made in the manner above described, in which 25 mils of this solution should require exactly 25 mils of the tenth-normal sodium thiosulphate V.S. to decolorize the mixture.

NOTE: When potassium permanganate V.S. is to be prepared for immediate use, this may be done as follows: Dissolve about 3.3 Gm. of crystallized potassium permanganate in 1000 mils of recently boiled and cooled distilled water. Then standardize this by either of the above methods and dilute accordingly with recently boiled and cooled distilled water. Potassium permanganate V.S. made by this method, without the preliminary boiling and standing, deteriorates readily, hence the titer should be verified each time it is used. Potassium permanganate V.S. should be kept in well-closed glass-stoppered bottles, and burettes provided with glass stop-cocks must be employed in titrating with it. This solution should be restandardized frequently.

Tenth-Normal Potassium Sulphocyanate Volumetric Solution

[VOLHARD'S SOLUTION]

KCNS = 97.18. 9.718 Gm. in 1000 mils.

Dissolve 11 Gm. of crystals of potassium sulphocyanate (see page 1688) in 1000 mils of distilled water. This solution is too concentrated and has to be adjusted so as to correspond in strength exactly with tenth-normal silver nitrate V.S. For this purpose, introduce into a flask 10 mils of tenth-normal silver nitrate V.S., 3 mils of ferric ammonium sulphate T.S., and 3 mils of nitric acid (free from nitrous compounds) and dilute the liquid with about 100 mils of distilled water. To this mixture add the sulphocyanate solution from a burette in small portions at a time. At first, a white precipitate of silver sulphocyanate appears, then every drop falling from the burette is surrounded by a deep brownish-red color produced by ferric sulphocyanate which disappears on vigorous shaking of the flask as long as any of the silver nitrate remains unchanged. When all of the silver has been converted into sulphocyanate, a single additional drop of the potassium sulphocyanate solution produces a brownish-red color which no longer disappears on shaking, but communicates a perceptible pale reddish-brown tint to the contents of the flask. Note the number of mils of the potassium sulphocyanate solution used and, after having confirmed the accuracy of the titration, dilute the whole of the remaining solution so that equal volumes of this and of the tenth-normal silver

nitrate V.S., at standard temperature, will be required to produce the permanent reddish-brown tint. (The same depth of pale reddish-brown tint to which the volumetric solution is adjusted must be attained when the solution is used for volumetric assays.) After the dilution, a new trial should be made, in which 25 mils of tenth-normal silver nitrate V.S., at standard temperature, 5 mils of ferric ammonium sulphate T.S., 5 mils of nitric acid, and 200 mils of distilled water are used, and there should be required of the potassium sulphocyanate solution, exactly the same number of mils as of the silver nitrate solution, at standard temperature, to produce the same depth of a permanent pale reddish-brown tint. If necessary a new adjustment should be made to render the correspondence perfect.

One Mil of Tenth-Normal Potassium Sulphocyanate V.S. is the equivalent of:

	Gramme.

Silver, Ag	0.010788
Silver Nitrate, $AgNO_3$	0.016989
Silver Oxide, Ag_2O	0.011588

Tenth-Normal Silver Nitrate Volumetric Solution

$AgNO_3 = 169.89.$ 16.989 Gm. in 1000 mils.

Into a flask containing 10.788 Gm. of silver (see page 1688), and provided with a small funnel inserted into the neck to prevent loss by spurting, introduce gradually about 30 mils of nitric acid (*Acidum Nitricum*, U.S.P.) or sufficient for complete solution. After thoroughly rinsing the funnel inside and outside, transfer the solution, which should be clear, with the rinsings of the flask to a beaker or porcelain dish and evaporate it to dryness on a water bath, carefully protecting the vessel from dust. Then after drying in an air-oven at about 120° C. (248° F.) for ten minutes, dissolve the residue in sufficient distilled water to measure exactly 1000 mils at standard temperature. Keep the solution in dark amber-colored, glass-stoppered vials, carefully protected from dust and sunlight.

NOTE: Titration by tenth-normal silver nitrate V.S. may be conducted in various ways, adapted to the special preparation to be tested.

A. The titration of soluble chlorides and bromides.—To the strictly neutral (to litmus) solution of an accurately weighed quantity of the salt contained in either a porcelain dish or a flask placed on a white surface add sufficient potassium chromate T.S. to impart a yellow tint, then slowly add the tenth-normal silver nitrate V.S. from a burette, stirring or agitating constantly until the mixture acquires a permanent red tint, due to the formation of red silver chromate. This method is only suitable for neutral solutions.

B. The titration of free hydrobromic, hydrochloric, and hydriodic acids or their salts in acid solution, known as the Volhard, Thiocyanate, or Sulphocyanate method of residual titration.—Add an accurately measured excess of tenth-normal silver nitrate V.S. to the solution of the halogen acid or its salt, and then acidify with nitric acid, and add a few mils of ferric ammonium sulphate T.S.; then determine the uncombined excess of the silver nitrate V.S. by titrating back with tenth-normal potassium sulphocyanate V.S., the end-reaction being the formation of a permanent pale reddish tint. The volume of the silver nitrate V.S. originally added, less that of the potassium sulphocyanate V.S. consumed, will give the number of mils of the former which were required for the precipitation of the halogen. The quantity of nitric acid added should be sufficient to remove the yellow color produced by the addition of the indicator.

C. Titration until the first appearance of a permanent precipitate.—This method is applicable in the estimation of the alkali cyanides and hydrocyanic acid. When the solution is used by this method, it is a fifth-normal instead of a tenth-normal solution.

Hundredth-Normal Silver Nitrate Volumetric Solution

$AgNO_3=169.89.$ 1.6989 Gm. in 1000 mils.

Dilute, at standard temperature, exactly 100 mils of tenth-normal silver nitrate V.S. with sufficient distilled water at the same temperature to measure 1000 mils.

This solution should be kept in glass-stoppered, amber-colored bottles which have been rinsed with nitric acid and then with hot distilled water until all traces of the acid have been removed.

One Mil of Hundredth-Normal Silver Nitrate V.S. is the equivalent of:

	Gramme.
Sodium Chloride, NaCl	0.0005846

Tenth-Normal Sodium Chloride Volumetric Solution

$NaCl=58.46.$ 5.846 Gm. in 1000 mils.

Dissolve 5.846 Gm. of sodium chloride (see page 1690) in sufficient distilled water to measure exactly 1000 mils at standard temperature.

Tenth-normal sodium chloride V.S. should correspond, volume for volume, with tenth-normal silver nitrate V.S., by titrating 20 mils of the former with the latter, using potassium chromate as indicator.

One Mil of Tenth-Normal Sodium Chloride V.S. is the equivalent of:

	Gramme.
Sodium Chloride, NaCl	0.005846
Silver, Ag	0.010788
Silver Nitrate, $AgNO_3$	0.016989
Silver Oxide, Ag_2O	0.011588

Double-Normal Sodium Hydroxide Volumetric Solution

$NaOH=40.01.$ 80.02 Gm. in 1000 mils.

Dissolve 90 Gm. of sodium hydroxide (*Sodii Hydroxidum*, U.S.P.) in sufficient recently boiled distilled water to measure about 1000 mils.

For the standardization of this trial solution of sodium hydroxide proceed as directed under normal potassium hydroxide V.S. (see page 1697); each 25 mils of the volumetric solution, at standard temperature, should exactly neutralize 9.407 Gm. of potassium bitartrate (see page 1687) or 50 mils of normal sulphuric acid V.S. (see page 1704).

NOTE: The same precautions should be taken for protecting this solution from the carbon dioxide of the air as are prescribed for normal potassium hydroxide V.S. (see page 1697).

Normal Sodium Hydroxide Volumetric Solution

$NaOH=40.01.$ 40.01 Gm. in 1000 mils.

Dissolve 50 Gm. of sodium hydroxide (*Sodii Hydroxidum*, U.S.P.) in sufficient recently boiled distilled water to measure about 1050 mils. For the standardization of this trial solution of sodium hydroxide, proceed as directed under normal potassium hydroxide V.S. (see page 1697); 25 mils of the volumetric solution, at standard temperature, must exactly neutralize 4.7035 Gm. of potassium bitartrate or 25 mils of normal sulphuric acid V.S. (see page 1704).

NOTE: The same precautions should be taken for protecting this solution from the carbon dioxide of

the air as are prescribed for normal potassium hydroxide V.S. (see page 1698). This solution may be employed in place of the normal potassium hydroxide V.S. (see page 1697), volume for volume.

One Mil of Normal Sodium Hydroxide V.S. is the equivalent of:

	Gramme.
Sodium Hydroxide, NaOH	0.04001

Tenth-Normal Sodium Thiosulphate Volumetric Solution

$Na_2S_2O_3+5H_2O=248.22.$ 24.822 Gm. in 1000 mils.

Dissolve 30 Gm. of sodium thiosulphate (see page 1691) in sufficient distilled water, previously boiled for twenty minutes in a flask of hard glass and quickly cooled, to measure 1000 mils. This trial solution, which is too concentrated, is standardized as follows:

To 25 mils of tenth-normal potassium dichromate V.S., accurately measured, at standard temperature, into a glass-stoppered flask of about 500 mils capacity, add about 2 Gm. of potassium iodide (*Potassii Iodidum*, U.S.P.) (free from iodate), followed by 10 mils of diluted sulphuric acid. Rinse the walls of the flask cautiously with about 200 mils of cold distilled water poured in carefully so as not to mix, thus protecting the lower layer from loss of iodine. Stopper the flask securely and set it aside for half an hour in a dark place, then carefully rinse the stopper and sides of the flask with distilled water and add slowly the trial solution of sodium thiosulphate, at standard temperature, while rotating the flask gently. When the solution has assumed a yellowish-green color, add starch T.S. and then reduce the flow of the sodium thiosulphate solution to drops, constantly shaking until the blue color of the mixture changes to a light green; note the number of mils of the trial sodium thiosulphate solution consumed. Then dilute the sodium thiosulphate solution with distilled water which has been previously boiled for twenty minutes so that equal volumes of it and the tenth-normal potassium dichromate V.S. will exactly correspond to each other under the above conditions, at standard temperature.

NOTE: The same precautions should be taken for keeping and protecting this solution from the carbon dioxide of the air as are directed under normal potassium hydroxide V.S. (see page 1698).

Two-Hundredth-Normal Sodium Thiosulphate Volumetric Solution

$Na_2S_2O_3+5H_2O=248.22.$ 1.2411 Gm. in 1000 mils.

Dilute exactly 25 mils, at standard temperature, of tenth-normal sodium thiosulphate V.S. with sufficient distilled water at the same temperature and recently boiled for twenty minutes to measure 500 mils. If desired, this solution may be standardized in the manner described under tenth-normal sodium thiosulphate V.S. (see above), employing 5 mils of tenth-normal potassium dichromate V.S. which should require for the decolorization of the liberated iodine, 100 mils of the two-hundredth-normal sodium thiosulphate V.S. The same precautions should be observed in the preservation of this solution as directed under tenth-normal sodium thiosulphate V.S.

One Mil of Two-Hundredth-Normal Sodium Thiosulphate V.S. is the equivalent of:

	Gramme.
Sodium Thiosulphate, $Na_2S_2O_3+5H_2O$	0.0012411
Iodine, I	0.0006346
Iodine, I (from Thyroid Glands)	0.0001058

Normal Sulphuric Acid Volumetric Solution

$H_2SO_4=98.09.$ 49.045 Gm. in 1000 mils.

Carefully mix 30 mils of pure, concentrated sulphuric acid (*Acidum Sulphuricum*, U.S.P.) with sufficient distilled water to measure about 1050 mils, and allow the liquid to cool to 25° C. (77° F.). Measure from a burette 25 mils of this liquid (which is yet too concentrated) into a flask, add about 50 mils of distilled water and 2 drops of methyl orange T.S. and afterwards, from a burette, a freshly standardized normal

potassium hydroxide V.S., shaking after each addition, and toward the end of the operation reducing the flow to drops, until the red tint of the solution changes to a permanent pale yellow after thorough shaking. Note the number of mils of normal potassium hydroxide V.S. consumed. Then dilute the sulphuric acid solution so that equal volumes of this and of normal potassium hydroxide V.S., at standard temperature, exactly neutralize each other.

ALTERNATIVE METHOD.—The diluted trial acid may be directly standardized as follows: Weigh accurately about 2 Gm. of anhydrous sodium carbonate (prepared as directed on page 1689), dissolve it in 100 mils of distilled water contained in a flask, add from 2 to 3 drops of methyl orange T.S., then run in, little by little, from a burette the acid solution to be standardized. Agitate the flask after each addition, reducing the flow of the acid to drops toward the end of the titration; the termination of the operation or exact saturation is indicated by a change in the color of the solution from orange to red or pink. A second or third trial should be made with other weighed portions of the sodium carbonate and in each experiment the number of mils consumed should be accurately noted and the results should agree closely. One gramme of anhydrous sodium carbonate requires for exact neutralization 18.868 (18.8679) mils of normal sulphuric acid V.S. at standard temperature.

EXAMPLE: 2.25 Gm. of anhydrous sodium carbonate required 37.6 mils of the trial acid for neutralization,[1] then:

$$42.453 : 37.6 :: 100 : x \quad x = 88.57 \text{ mils}$$

In a second trial 2.12 Gm. of the soda required 35.43 mils of the trial acid for neutralization, then:

$$40.00 : 35.43 :: 100 : x \quad x = 88.575$$

The acid may now be adjusted by measuring 885.72 mils (average) into a graduated liter flask and filling to the liter mark with distilled water at standard temperature. A new adjustment must be made to prove the accuracy of the standardization, using about 3 Gm., accurately weighed, of the sodium carbonate.

Half-Normal Sulphuric Acid Volumetric Solution

$H_2SO_4 = 98.09.$ 24.5225 Gm. in 1000 mils.

Dilute 500 mils of normal sulphuric acid V.S. at standard temperature with sufficient distilled water at the same temperature to measure 1000 mils.

This standard solution is chiefly employed in the titration of the organic salts of sodium and potassium in conjunction with methyl orange T.S. as indicator. For this purpose a special experiment should be made in which an accurately measured volume of 10 mils of normal potassium hydroxide V.S. should, after adding 2 drops of methyl orange T.S., require exactly 20 mils of the half-normal sulphuric acid V.S., at standard temperature, for neutralization. If necessary, an adjustment should be made to render the correspondence perfect.

Tenth-Normal Sulphuric Acid Volumetric Solution

$H_2SO_4=98.09$. 4.9045 Gm. in 1000 mils.

Dilute 100 mils of normal sulphuric acid, at standard temperature, with sufficient distilled water at the same temperature to measure 1000 mils.

ALTERNATIVE METHOD.—Mix about 5 mils of concentrated sulphuric acid (specific gravity 1.826 at 25° C. (77° F.)) with sufficient distilled water to measure about 1100 mils, and allow it to cool to 25° C. (77° F.). Standardization should be carried out as directed under the alternative method for normal sulphuric acid V.S. (see page 1704), employing about 0.3 Gm. of anhydrous sodium carbonate (see page 1689), accurately weighed, with methyl orange T.S. as indicator. One decigramme of anhydrous sodium carbonate should require for neutralization 18.868 (18.8679) mils of the tenth-normal acid V.S. at standard temperature. This standard solution is employed in conjunction with the fiftieth-normal potassium hydroxide V.S. in the titration of alkaloids, with cochineal, iodeosin, methyl red, or hematoxylin T.S. as indicator. For this purpose a special experiment should be made, in which an accurately measured volume of 10 mils of the tenth-normal sulphuric acid, after adding a sufficient quantity of the indicator to be employed, should require 50 mils of the fiftieth-normal potassium hydroxide V.S. at standard temperature for complete neutralization.

Fiftieth-Normal Sulphuric Acid Volumetric Solution

$H_2SO_4=98.09$. 0.9809 Gm. in 1000 mils.

Dilute 20 mils of normal sulphuric acid V.S., or preferably 200 mils of tenth-normal sulphuric acid V.S., at 25° C. (77° F.), with sufficient distilled water at the same temperature to measure 1000 mils. The strength of this solution must be adjusted so that 25 mils of it will exactly neutralize 25 mils of a recently

standardized fiftieth-normal potassium hydroxide V.S., at standard temperature, cochineal, iodeosin, methyl red, or hematoxylin T.S. being used as indicator.

Indicators

(U. S. P. IX)

NOTE: Each test solution used as indicator must be examined as soon as prepared, and afterwards, from time to time, as to its neutrality. If necessary, it is brought, by the cautious addition of highly diluted sulphuric acid or of a very dilute solution of an alkali, to such a point that when three drops of it are added to 25 mils of distilled water, a few drops of a hundredth-normal acid or alkali V.S., respectively, will distinctly develop the appropriate tints. Tests solutions are injured by exposure to light, and it is best to preserve them in dark amber-colored vials. Keep test papers in dark bottles.

Azolitmin.—A purified coloring matter from litmus. In very dark to black-violet scales or as a reddish-brown powder, slightly soluble in water, insoluble in alcohol or ether. To test its relative sensitiveness, prepare a solution of 0.1 Gm. of azolitmin in 40 mils of distilled water by the aid of a gentle heat, then add 10 mils of alcohol and filter the liquid when cold. To about 50 mils of distilled water, which has previously *been boiled* (to free it from dissolved carbonic acid) and quickly cooled, add 0.1 mil of the trial solution; the resulting bluish-red solution assumes at once a distinctly red color upon the addition of 3 drops of fiftieth-normal sulphuric acid V.S. and under the same conditions a bluish-violet color upon the addition of 0.5 mil of hundredth-normal sodium hydroxide V.S.

Azolitmin Test Solution.—Dissolve 1 Gm. of azolitmin in 80 mils of distilled water and 20 mils of alcohol in a flask and sterilize the solution by heating it in a current of steam for one hour.

Cochineal Test Solution.—Macerate 1 Gm. of unbroken cochineal (see page 363) during four days with 20 mils of alcohol and 60 mils of distilled water, then filter. The color of this test solution is turned violet by alkalies, and yellowish-red by acids. Cochineal T.S. is useful in titrating alkaloids, inorganic acids, ammonia, the alkalies, and alkaline earths. The presence of salts of iron, aluminum, or copper must be avoided. This indicator is useless for titrating organic acids.

Congo Red (Dianil Red, Kosmos Red Extra).—The sodium salt of benzidin-diazo-bis-1-naphthylamine-4-sulphonic acid, $(C_6H_4N : N.C_{10}H_5(NH_2)SO_3Na)_2$. A brownish-red powder, readily soluble in warm water, yielding a blood-red solution; slightly soluble in cold water, insoluble in ether or chloroform. The addition of tannic acid T.S. to an aqueous solution (1 in 20) intensifies the color of congo red but causes no precipitation (reaction for *basic color*). The addition of 5 mils of stannous chloride T.S. to 10 mils of an aqueous solution of congo red (1 in 10), followed by agitation and warming on a water bath, produces a violet precipitate. When filtered, the colorless filtrate does not again assume its red color when exposed to the air (test for *azo-group*). The addition of a 15 per cent. solution of sodium hydroxide to an aqueous solution of congo red (1 in 200) produces no change. The addition of hydrochloric acid to an aqueous solution of this dye (1 in 200) produces a violet precipitate. Concentrated sulphuric acid dissolves congo red with a slate blue color and, upon the cautious addition of distilled water, a blue precipitate is produced.

Congo Red Test Solution.—Dissolve 0.5 Gm. of congo red in 90 mils of distilled water and add 10 mils of alcohol. Add 2 or 3 drops of congo red test solution to 100 mils of distilled water contained in a porcelain dish; the red color of this solution changes to violet upon the addition of one drop of fiftieth-normal sulphuric acid V.S., and again changes to red upon the further addition of one drop of fiftieth-normal potassium hydroxide V.S. (*relative sensitiveness*).

Hematoxylin (Hydroxybrasilin), $C_{16}H_{14}O_6+3H_2O$.—A crystalline substance derived from the heartwood of *Hæmatoxylon Campechianum* Linné (Fam. *Leguminosæ*). Colorless to yellowish prisms; very slightly soluble in cold water or ether, readily soluble in hot water or alcohol. When exposed to light, hematoxylin acquires a red color and yields yellow solutions. In ammonia water or in carbonated or caustic alkali solutions it yields a purple solution. Keep hematoxylin and its solution protected from light and air. When dissolved in aqueous solutions of the following salts, hematoxylin develops the colors indicated: in alum solution a red color; in stannous chloride solution a rose color; in solutions of copper salts a greenish-gray color; and it gradually turns black in potassium dichromate solution.

Hematoxylin Test Solution.—Dissolve 0.02 Gm. of hematoxylin in 10 mils of alcohol. Use about 5 drops for each titration. This indicator assumes a yellow to orange color in acid solutions, and a violet to purple color in alkaline solutions. The titration is complete when the change in color remains permanent upon the addition of one drop of the volumetric solution after stirring the liquid.

Iodeosin (Tetraiodofluorescein), $C_{20}H_8I_4O_5$.—A scarlet, crystalline powder, soluble in alcohol with a deep red color and in ether with a yellowish-red color. It is insoluble in water containing a trace of hydrochloric acid. It is not suitable for use as an indicator unless a test solution prepared from it (see below) will stand the following test of sensitiveness: Into a well-rinsed, colorless, glass-stoppered flask, introduce 100 mils of distilled water containing 5 drops of iodeosin T.S. followed by about 30 mils of ether. Then add drop by drop from a burette hundredth-normal hydrochloric acid V.S., vigorously shaking it after the addition of each drop until the aqueous layer just becomes colorless. After the addition of 5 more drops of the iodeosin T.S. and again shaking, the aqueous layer does not acquire a pink color; should it do so, the color must be discharged upon the addition of 1 drop of hundredth-normal hydrochloric acid V.S. (test of *sensitiveness*).

Iodeosin Test Solution.—Dissolve 0.1 Gm. of iodeosin in 100 mils of alcohol. This indicator becomes colorless in acid solutions, changing to pink in alkaline solutions. Dilute the solution to be titrated with distilled water to about 100 mils, in a 200 mil flask, add 20 mils of ether and 5 drops of the iodeosin T.S., cork and shake it well. Then add the volumetric alkali solution gradually, shaking it well after each addition. The titration is complete when the lower aqueous solution retains a faint pink color after shaking thoroughly. For assaying alkaloidal residues, dissolve the latter in a measured excess of volumetric acid solution, and transfer the acid solution to a 200 mil flask, washing the container well with distilled water until the contents of the flask measure about 100 mils. Then proceed as above. Frequently a scum forms between the ethereal and aqueous layer, in which case this assumes a pink color before the latter.

Litmus Paper and Test Solution.—Exhaust powdered litmus with three separate and successive portions (each equal to about 4 times its weight) of boiling alcohol (which removes the undesirable color erythrolitmin), each extraction lasting for about one hour. After draining off the alcohol, digest the residue with about an equal weight of cold water and filter. (This blue solution, which contains some alkali, after being acidulated, may be used to make red litmus paper.) Finally, extract the residue with about 5 times its weight of boiling distilled water, and, after thoroughly cooling, filter. The addition of 1 drop of hundredth-normal acid or alkali V.S. to 50 mils of distilled water containing 5 drops of the indicator produces a distinct change in color. Preserve the filtrate, as a test solution, in wide-mouthed bottles stoppered with loose plugs of purified cotton so as to exclude dust but admit air. The latter must be free from acid or ammoniacal vapors. The blue color of litmus test solution is changed by acids to red, and this red color by the addition of alkalies is restored to blue.

Litmus Paper, Blue.—Impregnate with the test solution just described strips of white filter paper, and dry them by suspending them on lines of clean twine, in an atmosphere free from acid or ammoniacal vapors. This paper must quickly respond to a two hundred and fiftieth-normal acid V.S.

Litmus Paper, Red.—Prepare this with the same kind of paper and in the manner described under *Litmus Paper, Blue,* having added to the test solution used to impregnate the paper just sufficient of a highly diluted solution of hydrochloric acid to impart to it a faint red tint. Neither blue nor red litmus paper should have an intense color. Preserve the test paper in bottles, so as to exclude dust and acid or ammoniacal vapors. This paper must quickly respond to a two hundred and fiftieth-normal alkali V.S.

Methyl Orange (Helianthin, Orange III, Tropæolin D., Dimethylaniline Orange). The sodium salt of paradimethylaminoazobenzene sulphonic acid, $(CH_3)_2\text{-}N\text{-}C_6H_4\text{-}N=N\text{-}C_6H_4.SO_3Na$.—An orange-yellow powder, readily soluble in hot water, the solution on cooling separating golden-yellow scales. Slightly soluble in cold water, yielding an orange-yellow solution. Insoluble in alcohol. An aqueous solution (1 in 500), upon the addition of hydrochloric acid, yields a red precipitate soluble in excess of the acid with a deep red color. The addition of calcium chloride T.S. to the aqueous solution of methyl orange (1 in 500) precipitates the insoluble calcium salt. The addition of solution of lead subacetate (*Liquor Plumbi Subacetatis,* U.S.P.) precipitates the coloring matter from an aqueous solution. Sulphuric acid dissolves methyl orange with a blood-red color.

Methyl Orange Test Solution.—Dissolve 1 Gm. of methyl orange (see above) in 1000 mils of distilled water. Excessive quantities of this indicator should be avoided in titration; from 1 to 3 drops are sufficient for a volume of from 50 to 100 mils, or add just enough to impart a faint tint to the solution, which if alkaline or neutral will assume a pure yellow, if faintly acid, an orange, and when strongly acid, a rose red color. The solution must comply with the following requirements for sensitiveness as an indicator: To 100 mils of distilled water, contained in a flask of Jena glass, add 1 drop of the Test Solution; the pale yellow color of the solution, upon the addition of 0.5 mil of hundredth-normal sulphuric acid V.S. changes to a rose color; the yellow color will be restored upon the further addition of 0.5 mil of hundredth-normal potassium hydroxide V.S. Methyl orange is suitable for titrating inorganic acids, alkalies, alkali carbonates or bicarbonates. It is not to be employed in titrating organic acids, nor in alcoholic or boiling solutions. This indicator gives a yellow color with alkalies and rose color with acids.

Methyl Red (Paradimethylaminoazobenzeneorthocarboxylic acid), $(CH_3)_2\text{-}N\text{-}C_6H_4\text{-}N=N\text{-}C_6H_4.COOH$.—Violet crystals, very slightly soluble in cold water, yielding a red solution, readily soluble in alcohol and glacial acetic acid. When dissolved in sulphuric acid, methyl red shows the same color change as methyl orange. The applications of methyl red as indicator are the same as those of methyl orange, except that when titrating solutions containing carbonates it should not be used (see above).

Methyl Red Test Solution.—Dissolve 0.2 Gm. of methyl red in 100 mils of alcohol. As an indicator from 1 to 3 drops are sufficient for a volume of 100 mils, or add just sufficient to impart a faint tint to the solution, which if alkaline will assume a pure yellow, and when faintly acid a rose-red, or when strongly acid a violet-red color. The solution must comply with the following requirements for sensitiveness as an indicator: To 100 mils of distilled water which has been freed from carbon dioxide by boiling in a flask of hard glass, add 2 drops of methyl red T.S.; the yellowish-red color of 50 mils of this solution is changed to pure yellow by the addition of 2 drops of hundredth-normal potassium hydroxide V.S., and the color of the other 50 mils is changed to red by 2 drops of hundredth-normal hydrochloric acid V.S. Methyl red T.S., which is not affected by neutral salts, may be used in all instances where methyl orange is indicated, except where carbon dioxide is present; its end-points are sharper than those of methyl orange and it is far more sensitive in the titration of very dilute solutions of weak bases, surpassing hematoxylin or iodeosin in the titration of alkaloids.

Phenolphthalein Test Solution.—Dissolve 1 Gm. of phenolphthalein (see page 843) in 100 mils of alcohol. About 3 drops are sufficient for 50 mils of the solution to be titrated; it gives a red color with alkali hydroxides or carbonates, and acids render the solution colorless. The test solution must comply with the following requirements for sensitiveness as an indicator: From 3 to 5 drops of the test solution are added to 300 mils of distilled water which has been previously boiled and cooled in a flask of Jena glass; this solution is colored red by the addition of not more than 0.5 mil of hundredth-normal potassium hydroxide V.S. Phenolphthalein may be employed in hot titrations. It is not suitable as an indicator for ammonia nor in the presence of large quantities of ammonium salts, but is largely used for organic acids, alkali hydroxides, and for carbonates and bicarbonates in boiling solutions.

Phenolphthalein Paper is prepared by impregnating white, unsized paper with the test solution and drying it.

Rosolic Acid, Corallin.—Amorphous reddish-brown powder or lumps, the latter having a greenish, metallic luster, consisting chiefly of the compound $C_{20}H_{16}O_3$, isomeric with methylaurin and homologous with aurin. Rosolic acid is soluble in alcohol and insoluble in water.

Rosolic Acid Test Solution.—Dissolve 1 Gm. of rosolic acid in 10 mils of diluted alcohol, and add enough distilled water to make 100 mils. Of this solution, about 0.5 mil is used for 100 mils of solution to be titrated. Its color is pale yellow, unaffected by acids, but turning to rose with alkalies. The solution must comply with the following requirements for sensitiveness as an indicator: To 100 mils of distilled water, add 2 drops of the test solution; the pale yellow color of this solution, upon the addition of 0.5 mil of hundredth-normal potassium hydroxide V.S., changes to a rose-red; the yellow color will be restored upon the further addition of 0.5 mil of hundredth-normal sulphuric acid V.S. Ammoniacal solutions are to be highly diluted when titrated with this indicator. It is useful for mineral but useless for organic acids, except oxalic.

Turmeric Tincture.—Digest any convenient quantity of ground turmeric root (from Curcuma longa Linné, Fam. *Scitaminaceæ*) repeatedly with small quantities of distilled water and discard the liquids. Then digest the dried residue for several days with six times its weight of alcohol, and filter.

Turmeric Paper.—Impregnate white, unsized paper with the tincture, and dry it. The tincture, as well as the paper, turns brown with alkalies, and the original yellow color is restored by acids, with the exception of boric acid, which, especially in the presence of hydrochloric acid, turns the color to reddish-brown, which is changed to bluish-black by ammonia.

General Tests

(U. S. P. IX)

Under this head are placed tests which are frequently duplicated throughout this Pharmacopœia. In order to save space they are here grouped together and in the text are referred to by number.

1. Arsenic Test

(U. S. P. IX)

Test Apparatus.—Prepare several generators, equipped with tubes, etc., as described below. Select as a generator a bottle of about 50 mils capacity, having a mouth about 2.5 cm. in diameter, and provide a well-fitting rubber stopper, suitably perforated. In the perforation in this stopper insert a vertical exit tube about 13 cm. in total length and 1 cm. in diameter throughout the upper portion (for about 10 cm.) and constricted at its lower extremity to a tube of about 3 cm. in length and about 5 mm. in diameter. This latter tube should extend but slightly below the stopper. In the lower part of the wider exit tube insert a small pledget of dry glass wool (see page 1682) and then a strip of the freshly prepared but dry lead acetate test paper (see page 1683) rolled into a coil, and above this a plug of the moist (not wet) lead acetate glass wool (see page 1683). In the upper extremity of this tube insert, through a perforated cork stopper, a glass tube 12 cm. in length, having an internal diameter of about 3 mm. Place the mercuric bromide test paper (see page 1684) in this tube, bending or creasing the upper portion of the strip so that it will retain its position. The strip should extend within about 2 cm. of the perforated cork stopper and must not be introduced into the tube until ready to start the test. This tube should be thoroughly cleaned and dried each time it is used.

Standard Arsenic Test Solution.—Dissolve 0.1 Gm. of arsenic trioxide (see page 192), which has been finely pulverized, dried in a desiccator, and accurately weighed, in about 5 mils of a 20 per cent. solution of sodium hydroxide (free from arsenic). Neutralize the solution with diluted sulphuric acid (free from arsenic), add 10 mils of the same acid and sufficient recently boiled distilled water to bring the volume of the solution to exactly 1000 mils at 25° C. (77° F.). Accurately measure 10 mils of this solution, transfer it to a 1000 mil flask, add 10 mils of diluted sulphuric acid (free from arsenic) and make up the volume with recently boiled distilled water to exactly 1000 mils at 25° C. (77° F.). Employ this solution, containing 0.001 milligramme of arsenic trioxide in each 1 mil at 25° C. (77° F.), in preparing the standard stain. Keep this solution in a glass-stoppered bottle. It is advisable to make fresh solutions whenever new standard stains are to be prepared.

Preparation of the Chemical to be Tested.—Add 1 mil of a mixture of equal volumes of concentrated sulphuric acid (see page 1692) and distilled water, to 5 mils of an aqueous solution of the chemical (1 in 25) or to a solution in 5 mils of distilled water of the residue remaining after any special treatment that may be directed. This acidulation is not necessary in the case of inorganic acids. Now, unless specially directed, add 10 mils of a saturated aqueous solution of sulphurous acid (see page 1692). Evaporate this liquid in a small beaker, on a water bath, until it is free from sulphurous acid and has been reduced to about 2 mils in volume. Dilute this evaporated liquid to about 5 mils with distilled water.

The Test for Arsenic
(U. S. P. IX)

Preparation of the Standard Stain.—Introduce into the generator from 8 to 10 Gm. of zinc (see page 1692) followed by 25 mils of dilute sulphuric acid, prepared by mixing 1 part of concentrated sulphuric acid, free from arsenic (see page 1692), with 4 parts of distilled water, and 5 drops of acid stannous chloride T.S. (see page 1691). Add at once 2 mils [accurately measured at 25° C. (77° F.)] of the standard arsenic T.S. (see page 1709), and immediately insert the stopper containing the exit tube, into which have been placed the glass wool pledget, the dry lead acetate test paper, the moist lead acetate glass wool, and the mercuric bromide test paper, as described under the *Test Apparatus* (see page 1709). Should the evolution of the gas be violent at first, check the reaction by immersing the bottle in cold water. Should the reaction subside, increase it by placing the bottle in warm water. If the reaction be too violent, the stain will spread and not form a distinctive band, thus making the comparisons of color intensity difficult. After the test has continued for forty-five minutes, remove the mercuric bromide test paper and place it in a clean, dry tube for comparison. This stain represents 0.002 milligramme of arsenic trioxide in addition to any stain produced by the reagents. The stain from the reagents should scarcely be perceptible when determined by a blank experiment. Since light, heat and moisture cause the stain to fade rapidly, comparison should be made as soon as possible. The stained test papers may be preserved by either dipping in hot, melted paraffin or keeping them over phosphoric anhydride protected from light.

Testing the Chemical.—Introduce into another generator from 8 to 10 Gm. of the zinc, followed by 25 mils of the dilute sulphuric acid (1 to 4) and 5 drops of acid stannous chloride T.S. Insert the stopper containing the exit tube charged with the test papers and glass wool, as just described. Then add 5 mils of the solution to be tested, previously treated as directed, under *Preparation of the Chemical* (see page 1709), and immediately insert the stopper charged with the test papers and glass wool. When the evolution of hydrogen has proceeded actively for forty-five minutes, remove the mercuric bromide test paper and carefully compare it with the standard stain prepared as described above. The stain produced by the chemicals tested does not exceed in length or intensity of color that prepared as the standard, indicating not more than 1 part of arsenic in 100,000 parts of the substance tested.

Interfering Chemicals.—Antimony, if present in the substance tested, will produce a gray stain. *Sulphites, sulphides, thiosulphates*, and other compounds which liberate hydrogen sulphide or sulphurous acid when treated with sulphuric acid, must be oxidized by means of nitric acid and then reduced by means of sulphurous acid as directed under *Preparation of the Chemical to be Tested* (see page 1709), before introducing them into the apparatus. *Sulphur compounds* as well as *hydrogen phosphide* give a bright yellow band on the test paper. If sulphur compounds are present, a simultaneous darkening of the lead acetate test paper and glass wool will occur. If such is the case, the operation as directed under *Preparation of the Chemical to be Tested* (see page 1709) must be repeated upon a fresh portion of the solution being tested, using greater care in effecting the complete removal of the sulphurous acid. In testing hypophosphites special care should be observed to completely oxidize the solution being tested as directed, otherwise a yellow stain may be produced through the evolution of hydrogen phosphide, which might be confused with the orange-yellow color produced by arsenic. *Compounds containing antimony* should be tested for *arsenic* by Bettendorf's Test (see Test No. 2).

The test apparatus should be thoroughly cleaned and dried immediately before and after use.

2. Arsenic Test, Bettendorf's
(U. S. P. IX)

This test is employed only in testing salts of *bismuth* and compounds containing *antimony* for the presence of arsenic.

To a solution of the prescribed quantity of the substance to be tested in 5 mils of concentrated hydrochloric acid (see page 1682) contained in a clean test tube, add 10 mils of saturated stannous chloride T.S. (see page 1691) which has been freshly prepared, and set it aside for thirty minutes. If arsenic is present in non-permissible amounts, a brownish tint or precipitate will be seen when the tube is placed over a white surface and the solution viewed from above, comparison being made with a mixture of 5 mils of concentrated hydrochloric acid (see page 1682) and 10 mils of concentrated stannous chloride T.S., prepared as directed above.

Note: It is absolutely necessary that for this test the solution of stannous chloride be freshly prepared, and that nitrates, sulphates, sulphites, sulphides and compounds of mercury, gold, and selenium be absent from the reagents, and the chemicals being tested.

3. Test for Heavy Metals
(U. S. P. IX)

Chemicals.—This test is to be used to detect the presence of undesirable metallic impurities in official chemical substances or their solutions; these must not respond affirmatively within the stated time. Acidulate 10 mils of a solution of the substance in distilled water (1 in 50), contained in a test tube of about 40 mils capacity and of about 2.5 cm. diameter, with 1 mil of diluted hydrochloric acid (unless otherwise directed),[1] warm it to about 50° C. (122° F.), add an equal volume of freshly prepared hydrogen sulphide T.S., stopper, and allow the mixture to stand at 35° C. (95° F.) for half an hour. At the end of this time the mixture should still possess the odor of hydrogen sulphide; if not, it should be thoroughly saturated with the gas and again set aside for half an hour. The color produced, if any, is not greater than that observed by a blank test made in the same manner and with the same quantities of the reagents (omitting the solution

[1] First neutralize solutions of acids carefully by the addition of ammonia water and then acidify as above directed.

to be tested); the solutions being viewed crosswise by reflected light while held against a white surface. A slight turbidity due to separation of sulphur from the hydrogen sulphide may occur.

Volatile Oils.—Shake 10 mils of the oil with an equal volume of distilled water to which a drop of hydrochloric acid has been added and pass hydrogen sulphide through the mixture until it is saturated; no darkening in color will be produced in either the oil or the water (*lead or copper*).

4. Electrolytic Determinations

(U. S. P. IX)

Mercury and Zinc.—The electrolytic apparatus consists principally of an ammeter, voltmeter, and rheostat, properly connected with the source of the current, a platinum spiral anode and a device for rotating the anode.

The source of the current may be either storage batteries or any other system which permits the regulation of the voltage and amperage.

Mercury is determined in a mercury cathode cup. It consists of a glass cylinder about 6.5 cm. high and 3.5 cm. in diameter, into which is fused a platinum wire near the bottom, and containing 50–60 Gm. of pure mercury. The platinum wire must be in contact with the mercury.

For the determination of zinc, a nickel dish of about 175 mils capacity is used. A platinum dish upon which a thin layer of silver or copper has been previously deposited may also be used.

Corrosive Mercuric Chloride.—Dissolve 0.3 to 0.4 Gm. of the salt, accurately weighed, in 10 mils of distilled water and transfer the solution to the cathode cup, which has previously been weighed with its metallic mercury. Dilute the liquid to about 20 mils with distilled water, add 1 mil of nitric acid diluted with an equal volume of water and 10 mils of toluol, and pass through the solution a current of 1 to 3 amperes and 8 to 12 volts, stirring the solution by rotating the anode 500 to 600 revolutions per minute. After twenty minutes, when the mercury is all removed from solution (to be ascertained by removing a few drops of the solution and testing with hydrogen sulphide), wash with distilled water, with the aid of a siphon and without interrupting the current until the current drops to nearly zero. Remove the cathode cup, wash the mercury with alcohol, then with ether, remove most of the remaining ether with filter paper, then dry in a desiccator over sulphuric acid and weigh. The increase in the weight in the cathode cup represents the amount of mercury present in the quantity of the salt taken.

Mercury (Metallic), Mercuric Oxide (Red or Yellow), Mercury with Chalk and Solution of Mercuric Nitrate.—Dissolve an accurately weighed quantity of the substance in nitric acid (1 : 1) (mercury, metallic, or mercuric oxide 0.2 to 0.3 Gm. in 1 mil; mercury with chalk 0.6 to 0.8 Gm. in 2.5 mils; solution of mercuric nitrate 0.5 to 0.7 Gm. with 0.5 mil of nitric acid added), transfer the solution to the cathode cup which has previously been weighed with its metallic mercury, and dilute with distilled water to about 30 mils. Electrolyze the solution as described under *Corrosive Mercuric Chloride*, using a current of 1.5 to 2 amperes and 7 to 10 volts.

Ammoniated Mercury, Calomel, Mercuric Salicylate, Red Mercuric Iodide, Yellow Mercurous Iodide.—Introduce the accurately weighed substance (0.5 to 0.6 Gm. ammoniated mercury or calomel; 0.7 to 0.8 Gm. mercuric salicylate or yellow mercurous iodide; 1.0 to 1.2 Gm. red mercuric iodide) into the cathode cup, previously weighed with its metallic mercury, add 10 mils of solution of sodium sulphide (made by dissolving 50 Gm. crystallized sodium sulphide in sufficient distilled water to measure 100 mils) and dissolve as far as possible by agitation. Dilute the mixture to about 30 mils with distilled water and pass through the solution a current of 2 to 3 amperes and 7 to 10 volts for thirty minutes (or until a few drops of the liquid do not give a black precipitate or coloration when gently warmed with a few drops of concentrated ammonium chloride solution), stirring the solution by rotating the anode about 500 revolutions per minute. Wash the mercury, as described under *Corrosive Mercuric Chloride*, except that before washing with alcohol allow it to stand with about 20 mils of dilute acetic acid (from 2 to 3 per cent.) until bubbles cease to be evolved.

One gramme of Mercury is the equivalent of:

	Gramme.
Ammoniated Mercury, $HgNH_2Cl$	1.2566
Mercuric Chloride, Corrosive, $HgCl_2$	1.3535
Mercurous Chloride, Mild, $HgCl$	1.1768
Mercuric Iodide, Red, HgI_2	2.2654
Mercuric Nitrate, $Hg(NO_3)_2$	1.618
Mercuric Oxide (Red or Yellow), HgO	1.0798
Mercurous Iodide, Yellow, HgI	1.6327

Zinc.—Introduce into the weighed dish, an accurately weighed quantity of the salt, equivalent to about 0.15 Gm. metallic zinc (zinc acetate, 0.5 Gm.; zinc carbonate, 0.25 Gm.; zinc chloride, 0.3 Gm.; zinc oxide, 0.2 Gm.; zinc phenolsulphonate, 1.2 Gm.; zinc sulphate, 0.6 Gm.; zinc valerate, 0.7 Gm.); dissolve it in distilled water or in 10 mils of diluted sulphuric acid (zinc carbonate, zinc oxide), add from 30 to 35 mils of sodium hydroxide solution (20 per cent.) and dilute with distilled water to about 120 mils. Heat the mixture nearly to boiling and electrolyze for thirty minutes with a current of 4 to 5 amperes and 5 to 6 volts stirring the solution by rotating the anode 500 to 600 revolutions per minute. Without interrupting the current, wash the deposited zinc with distilled water with the aid of a siphon until the current drops to zero or nearly so. Remove the dish, wash the zinc first with alcohol then with ether, dry in a desiccator over sulphuric acid and weigh. The increase in the weight of the dish represents the amount of zinc present in the weight of the salt taken.

To determine zinc in zinc metal, weigh accurately about 1.5 Gm. of the metal, dissolve it by warming with 40 mils of diluted sulphuric acid, filter the solution, if necessary; wash the filter well with distilled water and make up the volume of the solution and washings to 100 mils. Measure 10 mils of this liquid into the weighed dish and proceed as directed above.

One gramme of Zinc is the equivalent of:

	Gramme.
Zinc Acetate, $Zn(C_2H_3O_2)+2H_2O$	3.3570
Zinc Chloride, $ZnCl_2$	2.0849
Zinc Oxide, ZnO	1.2448
Zinc Phenolsulphonate, $Zn(C_6H_5SO_4)_2+8H_2O$	8.5011
Zinc Sulphate, $ZnSO_4+7H_2O$	4.3988
Zinc Valerate, $Zn(C_5H_9O_2)_2+2H_2O$	4.6436

5. Assay for Chlorides, Bromides and Iodides
(U. S. P. IX)

Chlorides.—Dissolve about 0.2 Gm. of the salt to be assayed,[1] accurately weighed (corresponding to from 30 to 40 mils of tenth-normal silver nitrate V.S.), in 25 mils of distilled water in a 200 mil graduated flask. Add 50 mils of tenth-normal silver nitrate V.S. to the solution, and, after adding 5 mils of nitric acid, add sufficient distilled water to make 200 mils and mix the contents well. Then filter the mixture through a dry filter into a dry flask, and reject the first 20 mils of the filtrate. Add 2 mils of ferric ammonium sulphate T.S. to 100 mils of the subsequent filtrate and then titrate with tenth-normal potassium sulphocyanate V.S., until the supernatant liquid remains reddish after it is well shaken. Multiply the number of mils of tenth-normal potassium sulphocyanate V.S. required by 2 and subtract this figure from the number of mils of tenth-normal silver nitrate V.S. added. The difference, multiplied by the equivalent of the respective chloride (see page 1702) represents the amount of chloride present in the weight of the salt or solution taken.

Bromides and Iodides.—Dissolve about 0.4 Gm. of the salt if a bromide, or 0.5 Gm. of the salt if an iodide,[2] accurately weighed, in 25 mils of distilled water in a glass-stoppered flask. Add 50 mils of tenth-normal silver nitrate V.S. to the solution, then, after adding 2 mils of ferric ammonium sulphate T.S. and 2 mils of nitric acid, determine the excess of silver nitrate by titrating with tenth-normal potassium sulphocyanate V.S. until the supernatant liquid remains reddish after it is well shaken.

The difference between the number of mils of tenth-normal silver nitrate V.S. added and the number of mils of tenth-normal potassium sulphocyanate V.S. used, multiplied by the equivalent of the respective bromide or iodide being assayed (see page 1702) represents the amount of the bromide or iodide present in the weight of the salt taken. This difference, divided by the weight of the salt taken, represents the number of mils of tenth-normal silver nitrate V.S. required by 1 Gm. of the salt.

6. Assay for Alkali Salts of Organic Acids
(U. S. P. IX)

Heat about 2 Gm. of the salt to be assayed, accurately weighed, in a platinum or porcelain crucible, at first very gently, then gradually raise the temperature until the salt is thoroughly carbonized. (Do not use platinum crucibles for lithium salts.) The final temperature must not exceed a dull red heat and the flame of the burner must not come in contact with the carbonized mass. After allowing the carbonized mass to cool, disintegrate it with the aid of a stout glass rod and transfer the mass and crucible to a beaker. Add 50 mils of distilled water and 50 mils of half-normal sulphuric acid V.S., cover the beaker with a watch glass and boil the contents for thirty minutes. Then filter the solution and wash the residue with hot distilled water until the washings cease to redden blue litmus paper. Now determine the residual acid in the cooled filtrate by titration with half-normal potassium hydroxide V.S., using methyl orange T.S. as indicator. The difference between the number of mils of half-normal sulphuric acid V.S. added and the number of mils of half-normal potassium hydroxide V.S. used, multiplied by the respective equivalent of the salt (see page 1706) represents the amount of salt present in the amount taken.

7. Determination of Ash or Non-volatile Matter
(U. S. P. IX)

Chemicals.—Weigh accurately from 1 to 2 Gm. of the chemical or the amount directed in the text, and place it in a tared platinum or porcelain crucible. Ignite it, at first very gently, and then gradually raise the temperature until the carbon, if formed, is completely burned off. Conduct the ignition in a place protected from air currents and use as low a temperature as possible to effect the combustion of the carbon. When the carbon has completely disappeared, transfer the crucible while still hot to a desiccator and weigh it when cold. In the case of substances which increase in volume on ignition, or where it is very difficult to burn off the carbon, the determination is facilitated by using a platinum dish of suitable size, or by igniting the weighed quantity of the substance, in the manner described above, in several separate portions.

To test for non-volatile matter in volatile inorganic chemicals proceed as directed above, using as low a temperature as possible.

Vegetable Drugs.—Incinerate 2 Gm. of the ground drug until free from carbon and of constant weight, using a tared crucible and the lowest temperature possible, then determine the weight of the ash. If a carbon-free ash cannot be obtained in this way, exhaust the charred mass with distilled water, collect the insoluble residue on a filter paper of known ash content, incinerate the residue and filter paper until the ash is white or nearly so, then add the filtrate, evaporate it to dryness and heat the whole to a low redness. Finally determine the weight of the ash, deducting the weight of the ash from the filter.

8. Iodine Absorption Value
(U. S. P. IX)

The iodine value or number of a fat or oil indicates the proportion of iodine absorbed under specified conditions. It is determined as follows: Introduce about 0.8 Gm. of a solid fat or about 0.3 Gm.[3] of an oil, accurately weighed, into a glass-stoppered bottle of 250 mils capacity, dissolve it in 10 mils of chloro-

[1] Take 0.4 Gm. of solution of zinc chloride if assayed by this method.
[2] Take 0.7 Gm. of strontium bromide or strontium iodide.
[3] 0.15 to 0.18 Gm. for linseed oil, 0.18 to 0.2 Gm. for cod liver oil, and 0.8 to 1.0 Gm. for oil of theobroma.

form, add 25 mils of iodo-bromide T.S. (see page 1683), accurately measured from a burette or pipette, stopper the bottle securely, and allow the mixture to stand for half an hour[1] in a cool place protected from light. After this time it must still retain a brown color; if the color is not brown a new test should be started, using a smaller quantity of the fat or oil. Then add in the order named 30 mils of potassium iodide T.S., 100 mils of distilled water, and tenth-normal sodium thiosulphate V.S. in small, successive portions, shaking thoroughly after each addition, until the color of the mixture becomes quite pale. Then add a few drops of starch T.S. and continue the addition of tenth-normal sodium thiosulphate V.S. until the blue color is discharged. While this test is being carried out, make a blank test by mixing exactly the same quantities of iodo-bromide T.S. and chloroform and titrating the free iodine with tenth-normal sodium thiosulphate V.S. as directed above. The difference in the number of mils of tenth-normal sodium thiosulphate V.S. consumed by the blank test and the actual test, multiplied by 1.269 and divided by the weight of the fat or oil taken, gives the iodine value.

9. Saponification Value
(U. S. P. IX)

The saponification value of a fat or oil is the quantity of potassium hydroxide (expressed in milligrammes) consumed in saponifying 1 Gm. of the fat or oil. It is determined as follows: Weigh accurately, in a flask of 200 to 250 mils capacity, 1.5 to 2 Gm. of the filtered fat or oil and add to it 25 mils of alcoholic potassium hydroxide V.S. (see page 1700), accurately measured from a burette or pipette. Insert into the neck of the flask, by means of a perforated stopper, a glass tube from 70 to 80 cm. in length and from 5 to 8 mm. in diameter and heat the flask on a water bath for half an hour, frequently imparting a rotatory motion to the contents. Then add 1 mil of phenolphthalein T.S. and titrate the excess of potassium hydroxide with half-normal hydrochloric acid V.S. Make a blank test at the same time, using exactly the same amount of alcoholic potassium hydroxide V.S. The difference in the number of mils of half-normal hydrochloric acid V.S. consumed in the actual test and the blank, multiplied by 28.055 and divided by the weight of the fat or oil taken, gives the saponification value.

10. Acid Number for Resins
(U. S. P. IX)

The acid number of a resinous substance is the quantity of potassium hydroxide (expressed in milligrammes) required to neutralize 1 Gm. of the resinous substance. Dissolve in alcohol about 2 Gm. of the resinous substance to be tested, accurately weighed, add a few drops of phenolphthalein T.S. and titrate with half-normal potassium hydroxide V.S. The number of mils of half-normal potassium hydroxide V.S. required for neutralization, when multiplied by 0.028055 and the product divided by the weight taken, gives the acid number of the resin. The reaction is often more distinct if an excess of half-normal potassium hydroxide V.S. is used and the solution titrated back with half-normal acid V.S.

11. Determination of Crude Fiber
(U. S. P. IX)

Exhaust a weighed quantity of the ground material, representing about 2 Gm. of the drug, with ether or use the residue from the determination of the volatile extract soluble in ether (see below). Add 200 mils of boiling sulphuric acid solution, adjusted to exactly 1.25 per cent. by titration, to the ether-exhausted drug, in a 500 mil flask and connect the flask with a reflux condenser, the tube of which passes only a short distance below the rubber stopper, into the flask. Heat the mixture to boiling and continue the boiling during thirty minutes. Then filter the mixture through asbestos or glass wool and wash the residue on the filter with boiling distilled water until the washings are no longer acid. Rinse the residue back into the flask with 200 mils of boiling sodium hydroxide solution, adjusted to exactly 1.25 per cent. by titration, and free from sodium carbonate. Again heat the mixture to boiling and continue the boiling during thirty minutes under the reflux condenser as described under the treatment with acid, then rapidly filter through a tared filter, wash the residue with boiling distilled water until the washings are neutral, dry it at 110° C. (230° F.) until of constant weight and note the weight. Now completely incinerate the dried residue and weigh the ash; the loss of weight is considered to be the crude fiber.

12. Determination of Volatile Extractive, Soluble in Ether
(U. S. P. IX)

Extract completely 2 Gm. of the thoroughly dried and ground drug by subjecting it, during twenty hours, to the action of dehydrated ether (see page 1681) in a continuous extraction apparatus. Transfer the ethereal solution to a tared porcelain dish and allow it to evaporate spontaneously. Then dry it in a desiccator over sulphuric acid during eighteen hours and weigh the total ether extract. Now heat the extract gradually up to 110° C. (230° F.) until the weight becomes constant; the loss in weight during the heating represents the volatile portion of the extract.

13. Determination of Non-volatile Extractive, Soluble in Ether
(U. S. P. IX)

Proceed as directed under *Determination of Volatile Extractive, Soluble in Ether* (see No. 12). The weight of the extract after drying in a desiccator and then at 110° C. (230° F.) until of constant weight represents the non-volatile portion of the extract.

14. Determination of Alcohol in Official Preparations
(U. S. P. IX)

Place 25 mils of the preparation, measured at any definite temperature between 15° and 30° C. (59° and 86° F.), in a distilling flask of about 200 mils capacity, provided with a high side tube connected with

[1] One hour is required for castor oil and linseed oil.

a suitable condenser; add 50 mils of distilled water, distil into a 50 mil graduated flask, at such a rate that about 48 mils of distillate will be received in a half hour; if volatile products other than alcohol are known to be absent, bring to the original temperature and dilute with water of the same temperature to 50 mils.

Determine the specific gravity of the distillate at the same temperature at which the original sample was measured by means of a pycnometer or Westphal balance and find the per cent. of absolute alcohol by volume by reference to the alcoholometric table (page 1777), and multiply by the dilution factor to find the per cent. of alcohol in the original preparation.

If the preparation is suspected to contain less than 25 per cent. of alcohol, 50 mils should be taken for analysis; if it is suspected to contain over 50 per cent. of alcohol, 12.5 mils should be taken for analysis. In either case, the volume of the distillate should be made up as usual to 50 mils.

If the preparation contains iodine, combine it with zinc dust. (Sodium thiosulphate may be used instead of zinc dust, in which case several drops of sodium hydroxide T.S. should be added to prevent sulphur from distilling over.)

If volatile acids are present, neutralize with sodium hydroxide T.S.; if volatile bases are present, neutralize with dilute sulphuric acid; if both volatile acids and volatile bases are present, neutralize first with dilute sulphuric acid and distil about 50 mils, neutralize this distillate with sodium hydroxide T.S., and distil once more to obtain in the usual manner 50 mils.

If acetone, camphor, chloroform, ether, glycerin (30 per cent. or over), volatile oils or other volatile products are known or suspected to be present, transfer the first distillate to a separatory funnel and saturate it with sodium chloride, add 15 mils of petroleum benzin (boiling point 40°–50° C. (104°–122° F.)) and shake the mixture for one or two minutes. After the liquids have *completely* separated, draw off the lower alcoholic salt solution, with a second separator, and repeat the extraction with 15 mils of petroleum benzin; draw off the lower alcoholic salt solution into a distilling flask of about 200 mils capacity, wash the combined petroleum benzin solutions with about 25 mils of saturated sodium chloride solution and add the washings to the distilling flask. Distil into a 50 mil graduated flask at such a rate that about 45 to 48 mils of distillate are received within a half hour. Bring to the original temperature, dilute with water of the same temperature to 50 mils, and determine the specific gravity and alcoholic per cent. as directed above.

Alcoholic Content in Preparations

The figures given in the following table represent the average alcoholic content. It is impracticable to require an exact standard in alcoholic liquids made from drugs which contain varying proportions of moisture and extractive, and there is unavoidable loss of alcohol through evaporation during the manufacture and storage of preparations. In addition to this, allowance must be made in distillation for some loss incidental to the process, hence a tolerance of ten per cent. more or ten per cent. less than the figures given in the following table is permitted.

PER CENT. BY VOLUME OF ABSOLUTE ALCOHOL

Acidum Sulphuricum Aromaticum	85	Tinctura Cinchonæ Composita	64

15. Proximate Assays

(U. S. P. IX)

General Directions for Alkaloidal Assays

Nearly all alkaloids are practically insoluble in water, but they are more or less soluble in alcohol, chloroform, ether, amyl alcohol, benzene, petroleum benzin, or mixtures of several of these. The salts of the alkaloids, however, are mostly soluble in water, but practically insoluble in nearly all of the above mentioned solvents. The process of assay by immiscible solvents, which is generally known as the "shaking out" process, is based on this property of alkaloids, and it is carried out by treating the drug or a concentrated liquid extract with a solvent immiscible with water, in the presence of an excess of alkali, which liberates the alkaloid. The free alkaloid is dissolved by the immiscible solvent, which is then transferred to a separator and shaken with an excess of acid diluted with water.

When a drug to be assayed is directed to be made from a powder of a certain degree of fineness it is understood to mean that it must not be coarser than the size directed; a finer powder may, however, be used.

If the immiscible solvent is specifically heavier than water (*e.g.*, chloroform, or a mixture of more than one volume of chloroform to one volume of ether) it will separate in the bottom of the separator. It is then drawn off into another separator and shaken with successive portions of weak acid until the alkaloid is all removed.

If the immiscible solvent is specifically lighter than water (*e.g.*, ether, or a mixture of more than two volumes of ether with one volume of chloroform) it will, on separation, form the upper liquid. The lower acid liquid is then drawn off and preserved, and the residual immiscible solvent shaken with successive portions of weak acid until wholly free from alkaloid.

The volume and strength of the acid to be used is left to the discretion of the operator. It is best, however, to keep the total volume as small as possible. For the first extraction, it is advisable to use 10 mils of half-normal acid V.S. or sufficient to render the mixture distinctly acid; for the second extraction, use 5 mils of half-normal acid V.S. and 5 mils of distilled water. Repeat the extraction with the same proportion of acid and distilled water. In all assays, the extraction should be continued until 0.5 mil of the acid washings shows only a very faint cloudiness on the addition of a drop of mercuric potassium iodide T.S., or, in the case of caffeine and colchicine, on the addition of a drop of iodine T.S.

The united solutions containing the alkaloid in the form of a salt are shaken thoroughly with ether and allowed to stand at least fifteen minutes for complete separation. The acid solution is then drawn off into a second separator, the ether washed with a little water and this wash water added to the acid solution. The acid solution is then made alkaline, in most cases with ammonia water, and shaken out with several successive portions of the appropriate immiscible solvent. The volume of the latter to be used in each operation is not less than half that of the acid solution, and the operation must be repeated as long as any alkaloid is extracted by the immiscible solvent. To test this, evaporate 1 mil of the last extraction and dissolve the residue in a few drops of diluted hydrochloric acid; the resulting solution should show not more than a very faint cloudiness on the addition of a drop of mercuric-potassium iodide T.S., or, in the case of caffeine and colchicine, on the addition of a drop of iodide T.S. The number of extractions required depends largely on the character of the alkaloid. With most alkaloids it is advisable to "shake out" three or four times before testing. Physostigmine and pilocarpine require about twice as many extractions as most other alkaloids.

After having drawn off from a separator any liquid containing an alkaloid, a fresh portion of the solvent should be immediately added to the contents of the separator, and, before shaking, about 1 mil of this should be drawn off to wash out the stem of the separator. In the case of volatile solvents, the outside of the stem of the separator should also be washed by dipping it in the portion of the fresh solvent to be used for the next shaking out operation. Before evaporation the final ether or chloroform solution should be filtered through a dry filter, or preferably through a pledget of purified cotton. When filtering volatile solvents containing alkaloids through a paper filter, the upper edge of the filter should not reach the top of the funnel and the filter should be kept constantly full of the liquid until all has been added, then covered until the last of the liquid has passed through. Finally the filter should be washed thoroughly by applying portions of the volatile solvent to the top and carefully washing the outside of the funnel stem. Immiscible solvents heavier than water may be conveniently filtered by packing the stem of the separator below the stopcock with purified cotton before drawing off the solvent. The alkaloidal solution is finally evaporated cautiously to expel the solvent, and the residue either dried to constant weight and weighed, or more commonly titrated with volumetric acid.

When using aliquot parts, the solvent and the aliquot part should be measured at the same temperature. When pouring volatile liquids, the lower the temperature at which the operation can be conducted, the less the danger of loss from evaporation.

The shaking or rotation with an immiscible solvent should ordinarily be continued about one minute. Long or violent agitation should be avoided, as emulsions are apt to form. Should a partial emulsion form it may be broken up by drawing off the clear portion, introducing a tuft of cotton and with a glass rod moving the cotton about in the emulsion next to the surface of the separator. Should the emulsion prove persistent, draw off the emulsified portion and evaporate the volatile solvent. The resulting residue, if alkaline, should be washed with each successive portion of the solvent used in extracting the original solution. If acid it should be washed with acidulated water.

Emulsions are less apt to form in strongly acid or alkaline solutions than in those which are neutral or slightly acid or alkaline. Emulsification is sometimes prevented by increasing the volume of the aqueous or of the immiscible solvent. Chloroform or ether solutions of drugs rich in fat form very troublesome emulsions. In such cases it is advisable to add about 10 mils of normal sulphuric acid V.S., and evaporate the volatile solvent, stirring with a rubber-tipped glass rod. When the resinous and fatty matter has been agglutinated, cool the acid solution and filter it through a small wetted filter into a separator. Redis-

solve the residue in 15 mils of ether, add 5 mils of tenth-normal acid V.S., evaporate the ether as before, with continued stirring, and pour the acid solution through the filter into the separator. Repeat the extraction of the fatty residue with dilute acid two or three times and finally wash the filter free from alkaloids. Then make the solution in the separator alkaline, and "shake out" with the immiscible solvent in the usual manner.

The stems of separators and funnels and the lips of flasks, separators and graduates, from which volatile solvents containing alkaloids have been poured or drawn off, should be carefully washed to prevent loss and to remove any of the alkaloids left by evaporation, and the washings should be added to the solvent.

An alkaloidal residue to be determined volumetrically should be softened by the addition of about 1 mil of neutral alcohol or ether, the required amount of standard acid added, and the mixture gently warmed to insure the complete solution of the alkaloid. Finally add a sufficient quantity of distilled water to make the volume of the liquid for titration measure about 25 mils. When the residue is to be weighed, if the final solvent has been chloroform, the last traces of that solvent should be removed by the addition of a little ether or alcohol followed by evaporation; care being taken to avoid loss by decrepitation, especially when evaporating a chloroformic solution of nux vomica or of cinchona alkaloids. This may usually be prevented by the addition of a little alcohol after the solution has been reduced to a volume of one or two mils.

If preferred, methyl red T.S. may be used in place of cochineal T.S. for alkaloidal titration, in which case the volumetric solution should have been standardized by the use of methyl red T.S. If this has not been done a blank titration should be made to determine the factor for the tenth-normal sulphuric acid V.S., using methyl red T.S. as the indicator.

16. Melting Points

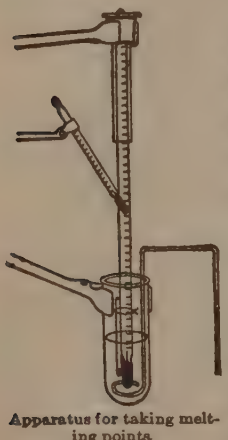
(U. S. P. IX)

For the purpose of the Pharmacopœia the melting point is defined as that interval of temperature within which the substance is observed to melt when treated as directed below.

For the determination of the melting point, Pharmacopœial substances are divided into two classes:

Class I.—Substances readily reduced to a powder.

Class II.—Substances not readily reduced to a powder, such as fats, fat acids, paraffin, petrolatum and waxes.



Apparatus for taking melting points

Apparatus required (see illustration):

1. *A round-bottom, glass tube* of 30 mm. internal diameter and about 10 cm. long, flaring slightly at the top like an ordinary test tube. The walls of the tube are not more than 1.5 mm. thick at any point. The tube is made of glass which will stand heating over an open Bunsen flame.

2. *A stirring device*, which can be made from a glass rod of about 2 mm. external diameter. It is made circular at the end to fit the container (1) and is bent twice at right angles above the top of the container to bring its outer end conveniently to hand for manipulation.

3. *A standard thermometer* covering the desired range of temperature (see page 1724).

4. *An auxiliary thermometer* (see page 1724).

5. *A capillary glass tube* about 6 cm. long and from 0.8 to 1.2 mm. internal diameter, the walls from 0.2 to 0.3 mm. thick and the tube closed at one end.

Procedure for Class I:

Reduce the substance to a No. 100 powder and, unless otherwise stated, render it anhydrous, when it contains water of crystallization, by drying it at the temperature given in the text, or, when the substance contains no water of crystallization, by drying it for twenty-four hours over sulphuric acid.

Select a bath suitable for the melting temperature to be determined, and fill the container to a depth which will permit of such immersion of the thermometer that the upper end of the bulb will be from 2 to 3 cm. below the surface of the bath and the lower end of the bulb about equally distant from the bottom of the container.

Charge a capillary glass tube with sufficient of the dry powder to form a column in the bottom of the tube from 2.5 to 3.5 mm. high when packed down as closely as possible by moderate tapping on a solid surface. Attach the capillary tube to the thermometer by wetting both with the liquid of the bath or by means of a piece of platinum wire and adjust it so that the substance is centrally located by the side of the thermometer bulb. Heat the bath by means of a free Bunsen flame until a temperature 25° C. (77° F.) below the supposed melting point is reached, then carefully regulate the rate of rise in temperature to about 3° per minute until the substance begins to melt (the temperature at which the column of the substance is observed to definitely collapse against the sides of the tube at any point is defined as the beginning of melting), and from that time carefully regulate the rise in temperature to about 0.5° per minute until melting is complete (the temperature at which the substance becomes liquid throughout is defined as the end of melting). The bath must be stirred constantly throughout the heating.

The result thus obtained as the melting interval must be adjusted by applying the calibration correction and that for the emergent stem, as follows:

Attach the auxiliary thermometer, as shown in the illustration, so that the center of its bulb is as close as possible to the stem of the main thermometer at a point midway between the surface of the bath and the supposed melting point. In order to prevent the heat from the burner or currents of cold air from affecting the temperature of the auxiliary thermometer, it is advisable to adjust to the stem of the main thermometer a movable platform made of stiff paper, having its edges folded so as to form a box-like shield

surrounding the bulb of the auxiliary thermometer. Note the temperature registered by the auxiliary thermometer at the end of the melting of the substance and calculate the emergent stem correction by the following formula:

$$\text{correction} = 0.00015 \times N\ (T - t)$$

in which N represents the number of degrees of emergent stem from the bath, T the temperature at the end of melting, and t the temperature registered by the auxiliary thermometer; the correction to be added to the observed reading of the main thermometer.

To avoid the necessity of determining the emergent stem correction each time a melting point is taken, the corrections for intervals of 10° C. (50° F.) may be determined at about 25° C. (77° F.) room temperature and the results plotted on cross-section paper, the temperature of the bath represented by the abscissæ and the amount of correction by the ordinates. The correction for any intermediate temperature can then be interpolated.

NOTE: Suggestions regarding liquids to be used for baths in Class I:

For temperatures up to 200° C. (392° F.) a purified, concentrated sulphuric acid is a suitable bath. For higher temperatures, up to about 350° C. (662° F.) a pure grade of cotton seed oil (almost colorless) will serve for a limited number of determinations. Other, though less desirable, substitutes for sulphuric acid at high temperatures are: (1) a pure grade of paraffin which has been freshly distilled; (2) clean, white, artificial (cotton seed) lard. A very desirable bath for high temperature work is prepared by cautiously boiling together, for five to ten minutes under a hood, a mixture of 70 parts of purified concentrated sulphuric acid and 30 parts of potassium sulphate, stirring constantly until the sulphate is completely dissolved.

Procedure for Class II:

Carefully melt the substance to be tested at as low a temperature as possible and draw it into a capillary tube which is open at both ends, to a depth of about 10 mm. Cool the charged tube at 10° C., (50° F.) or lower, for twenty-four hours, or in contact with ice for at least two hours. Then attach the tube to a standard thermometer by means of a rubber band, adjust and heat it in a water bath, as directed in Class I, except that, within 5° of the assumed melting temperature, the rate of rise of temperature is carefully regulated to about 0.5° per minute.

The temperature at which the substance is observed to rise in the capillary tube is taken as the melting point.

17. Boiling Points

(U. S. P. IX)

The boiling point is defined as that range of temperature within which at least 95 per cent., by volume, of the substance distils, when treated as directed below.

Apparatus Required.—A distilling bulb of from 50 to 60 mils capacity to the lower part of the neck, the length of the neck from 10 to 12 cm. and the internal diameter from 14 to 16 mm. The outlet tube of from 4 to 5 mm. internal diameter should be attached to the neck at approximately its midpoint, forming an angle of from 70° to 75° with the lower end of the neck.

A straight glass condenser with a water jacket from 40 to 60 cm. in length; the distance from the upper end of the water jacket to the neck of the bulb being from 18 to 25 cm.

Thermometer.—In order to avoid the necessity of an emergent stem correction, it is advisable that an accurately standardized thermometer of the Anschutz type be used. If such a thermometer is not available, a thermometer used for melting points (see page 1716) may be employed, applying the emergent stem correction as described under *Melting Points* (see above), the length of emergent stem being measured, in degrees, from the lower end of the stopper to the highest point of the boiling temperature. When placed in position the lower end of the thermometer is 2 to 3.5 cm. below the center of the orifice of the outlet tube.

An asbestos board, of from 12 to 15 cm. square and from 3 to 5 mm. in thickness, having a circular perforation, located centrally, for the reception of the bulb. The edge of the asbestos around the perforation should fit closely to the bulb when the latter is set into it. The size of the perforation should be such that, when the bulb is set into it, the portion of the bulb below the upper surface of the asbestos will have a capacity of from 3 to 4 mils.

Procedure.—Place the asbestos board on a tripod or other suitable support. Introduce into the distilling bulb 25 mils of the liquid to be tested, insert the thermometer, stand the bulb in an upright position in the perforation of the asbestos board and connect it with the condenser. Then distil the liquid at the rate of 1 mil for each fifteen to twenty seconds, noting the temperature as soon as 5 drops of the liquid have distilled into the receiver and when 95 per cent. of the original volume has distilled. Correct the reading for any difference in the barometric pressure by allowing 0.1° C. (32.18° F.) for each 2.7 mm. difference from the standard pressure of 760 mm., adding if the pressure is lower, and subtracting if higher.

NOTE: In order to have the entire distillate distil over at the prescribed rate, it is best to make a preliminary distillation of a separate portion of 25 mils of the liquid, during which the source of heat (a good Bunsen burner) is regulated so that the distillation proceeds at the prescribed rate. Having thus regulated the burner, temporarily remove it, clean the bulb, recharge it with a fresh portion of 25 mils of the liquid and proceed with the distillation as described above.

18. Congealing Points

(U. S. P. IX)

Unless otherwise directed, about 10 mils of the liquid to be tested is introduced into a dry test tube of from 18 to 20 mm. internal diameter, which is then cooled in water or a suitable freezing mixture, the temperature of which should be about 5° lower than the supposed congealing point of the liquid. To induce

crystallization, rub the walls of the tube with a standard thermometer (see page 1724), or add a small crystal of the substance being tested. By alternated immersion of the tube in the bath, or removal from the bath and constant stirring with the thermometer, the temperature is so adjusted that the greater part of the liquid gradually congeals. The highest temperature remaining constant for a short time during the congealing is defined as the congealing point.

19. Solubilities

(U. S. P. IX)

The statements concerning solubilities quoted in this Pharmacopœia are not intended as physical constants in the strict sense of this term, but primarily as information required by physicians and pharmacists in connection with the preparation and dispensing of medicines.

The following points must be observed in the accurate determination of solubilities: 1. Purity of both the dissolved substance and solvent is essential since impurities in either affect the solubility to a greater or less extent. 2. The constancy of the temperature must be accurately maintained during the course of the determination. 3. Complete saturation must be secured. 4. Accurate analysis of the saturated solution and correct expression of the results are imperative. In connection with the above named essential features of a correct solubility determination, attention should be called to the varying rates of solution of different compounds, and to the marked effect of the degree of fineness of the particles upon the time required for the saturation of the solution. In general, it may be said that an equipment comprising a thermo-regulator and a constant agitation device is indispensable for accurate solubility determinations. The solubility of Pharmacopœial compounds in given solvents is considered to be of minor importance as a means for their identification or quantitative estimation, as the other tests contained in the description of each article in the text cover both identity and purity.

The solubility data given throughout this volume have for the most part been determined under the above described conditions, and will, therefore, frequently show a somewhat greater solubility than would be found in the daily experience of most pharmacists.

Method for Determining Solubilities.—In brief, this consists in preparing a saturated solution of the given substance and ascertaining, by analysis, the amount present in a definite quantity of the solution. Complete saturation can be attained most readily by constant stirring or agitation by means of a suitable mechanical contrivance. A simple apparatus for this purpose consists of a test tube of medium size fastened upright in a water bath maintained at constant temperature. The solvent and excess of solids are placed in the tube and stirred by means of a motor-driven rotating glass spiral. After a given period of stirring a definite weight of the clear solution is analyzed and the stirring continued for an additional period of several hours. If analysis shows no increase of dissolved substance after the second period of stirring, the result is to be taken as the solubility at the particular temperature. Minute details of methods for determining solubilities are described in Bulletin No. 67 of the Hygienic Laboratory, U. S. Public Health Service.

20. Gasometric Estimations

(U. S. P. IX)

In certain cases the Pharmacopœia directs the strength of a product or chemical substance to be determined by the volume of gas (nitrogen dioxide) given off during a definite reaction. This volume is to be determined by the use of the nitrometer in the following manner:

Arrange a nitrometer consisting of a measuring tube (graduated into one-tenth milliliter divisions and having a capacity of at least 50 mils) connected by stout rubber tubing with an open equilibrium tube (both tubes, preferably, provided with a globular expansion near the lower end) in such a manner, by suitable clamps attached to a stand, that either tube may be readily and quickly clamped at a higher or lower level. The stop-cock of the measuring tube having been opened, and the open equilibrium tube having been raised to a higher level, pour into the latter a saturated aqueous solution of sodium chloride, until the measuring tube, including the bore of the stop-cock, is completely filled. Then close the latter and adjust the equilibrium tube at a low level. Having ascertained that the stop-cock is closed and is air tight, and having, if necessary, wiped out the graduated tube of the nitrometer, introduce into it the prescribed quantity of the liquid to be tested, and allow this to flow slowly into the measuring tube, being careful not to admit any air. Follow it by the prescribed quantities of the several reagents (potassium iodide T.S. and normal sulphuric acid V.S.). When the reaction (which takes place at once) moderates, remove the measuring tube from its clamp, and, being careful to hold it constantly so that the liquid contained in it stands at a higher level than that in the equilibrium tube, shake its contents, without permitting any gas to pass into the open tube. When the reaction has completely ceased and the volume of gas has become constant, which usually requires from thirty to sixty minutes, restore the tube to its fastening, and allow the apparatus and contents to acquire the ordinary temperature of the room, which is assumed to be at or about 25° C. (77° F.). Then adjust the two tubes so that the liquid columns are at exactly the same level, and read off the volume of gas in the measuring tube. Multiply this figure by the weight of the liquid being assayed which is the equivalent of 1 mil of nitrogen dioxide (see page 1719). The result will be the weight of the absolute substance (ethyl, amyl, or sodium nitrite) contained in the quantity taken for the assay.

For pharmacopœial purposes the determination will be sufficiently exact if the evolved gas be measured within 3 degrees above or below 25° C. (77° F.).

Since temperature and barometric pressure affect the volume of the gas, the following correction factors must be used to obtain exact results when the temperature and pressure are not nearly normal. The barometer correction is important at any locality more than 250 meters above sea-level:

Factors for Temperature Corrections

Normal Temperature, 25° C. (77° F.)

Temperature.	Factor.	Temperature.	Factor.	Temperature.	Factor.
15° C.	1.035	22° C.	1.010	29° C.	0.987
16° C.	1.031	23° C.	1.007	30° C.	0.983
17° C.	1.028	24° C.	1.003	31° C.	0.980
18° C.	1.024	25° C.	1.000	32° C.	0.977
19° C.	1.021	26° C.	0.997	33° C.	0.974
20° C.	1.017	27° C.	0.993	34° C.	0.971
21° C.	1.014	28° C.	0.990	35° C.	0.968

Example: Assuming that the volume of gas read off was 44.5 mils at 32° C. (89.6° F.) and it is desired to ascertain the corresponding volume at 25° C. (77° F.), barometric pressure not being taken into consideration, then the 44.5 mils must be reduced in the proportion of 1 to 0.977 (see temperature correction factors above), or 44.5 must be multiplied by 0.977. The result will be 43.48 (more exactly 43.4765) mils as the equivalent volume of gas at 25° C. (77° F.).

Factors for Correction for Barometric Pressure

(Normal Barometer, 760 mm.)

Barometer Reading.		Factor	Barometer Reading.		Factor.
Millimeters.	Inches.		Millimeters.	Inches.	
790	31.10	1.039	660	25.98	0.868
780	30.71	1.026	650	25.59	0.855
770	30.31	1.013	640	25.20	0.842
760	29.92	1.000	630	24.80	0.829
750	29.53	0.987	620	24.41	0.816
740	29.13	0.974	610	24.02	0.803
730	28.74	0.961	600	23.62	0.789
720	28.35	0.947	590	23.23	0.776
710	27.95	0.934	580	22.83	0.763
700	27.56	0.921	570	22.44	0.750
690	27.17	0.908	560	22.05	0.737
680	26.77	0.895	550	21.65	0.724
670	26.38	0.882	540	21.26	0.711

Example: Assuming that the volume of gas read off was 43.48 mils at 590 mm. barometric pressure, and it is desired to ascertain the corresponding volume at normal barometric pressure (760 mm.), temperature not being taken into consideration, then the 43.48 mils must be reduced in the proportion of 1 to 0.776 (see barometric correction factors above), or 43.48 must be multiplied by 0.776. The result will be 33.74 mils as the equivalent volume of gas at normal barometric pressure.

Estimation of Nitrogen Dioxide

NO = 30.01; 1 Liter { at 0° C. (32° F.) and 760 mm. = 1.3406 Gm.
at 25° C. (77° F.) and 760 mm. = 1.2281 Gm.

One Milliliter of Nitrogen Dioxide is the equivalent of:

	At 0° C. (32° F.) and 760 mm. Gramme.	At 25° C. (77° F.) and 760 mm. Gramme.
Nitrogen Dioxide, NO = 30.01	0.0013406	0.0012281
Amyl Nitrite, $C_5H_{11}NO_2$ = 117.10	0.0052310	0.0047920
Ethyl Nitrite, $C_2H_5NO_2$ = 75.05	0.0033528	0.00307127
Sodium Nitrite, $NaNO_2$ = 69.01	0.0030828	0.0028241

21. Optical Rotation

(U. S. P. IX)

In a ray of ordinary light the transverse vibrations take place indifferently in any plane about the line of propagation. When these waves are limited to a single plane they are termed polarized and the phenomenon is known as polarization.

Many organic substances either liquid or in solution in suitable solvents, when examined in a specially constructed optical apparatus called a polariscope, are capable of rotating the plane of polarization of a ray of light either to the right or to the left. Such substances are termed "optically active," and when rotating to the right are designated as "dextrorotatory" and when rotating to the left as "lævorotatory." Substances which do not possess this property of optical rotation are termed "optically inactive." Optical activity in many instances is intimately connected with the chemical constitution of a substance and it frequently becomes a specific property and its determination is of considerable value.

Among the substances recognized by this Pharmacopœia, there are several, particularly certain essential or volatile oils and related bodies, for which the determination of the angle of rotation of a ray of polarized light, or, in some cases, the proof of their optical inactivity, affords the most simple and positive evidence of their identity or purity.

The instruments used for this purpose vary somewhat in their construction and are classified as polarimeters measuring angular rotation and saccharimeters measuring percentage of sugar. Those which are most generally adapted for the examination of the substances mentioned above are the penumbral or so-called " half-shadow " instruments of Laurent and of Schmidt and Hänsch in which the two sides of the field of vision are capable of becoming unequally illuminated. Polarimeters permit the angle of rotation to be read off in degrees or fractions of a degree of a circle. Saccharimeters, set to measure percentage of sucrose, give readings in terms of divisions of the sugar scale.

These determinations are best made in a dark room, and by means of monochromatic light, the latter being obtained by introducing into a non-luminous flame, on a loop of platinum wire, a small bead of fused sodium chloride. The light thus radiated corresponds with the line D of the solar spectrum.

The following factors are employed for converting readings of a saccharimeter into readings of a polarimeter.

1 division Laurent sugar scale equals 0.2167° angular rotation D.

1 division Schmidt and Hänsch sugar scale equals 0.346° angular rotation D.

Since the deviation of the plane of polarization either to the right or to the left of the zero point is directly proportional to the length of the column of liquid, it is important that the observations should be made with tubes of a definite length, such as 200, 100, 50, or 25 mm. The selection of the length of the tube to be employed is, however, usually dependent upon the depth of color of the liquid and the magnitude of its optical rotation.

The rotatory power of an optically active, liquid substance, observed with sodium light, and referred to the ideal density 1, and in a tube having a length of 1 decimeter (100 mm.), is designated as its *specific rotatory power*. This is usually expressed by the term $[\alpha]_D$. Since, however, not only the density of an optically active liquid, but also its rotation, is influenced by the temperature, the specific rotation varies with the latter. In stating the specific rotation it is, therefore, necessary to indicate at what temperature the rotation and the density of the liquid have been determined. But for the same temperature the specific rotation of a pure, optically active liquid is always a constant number. The temperature used in the text of this Pharmacopœia is 25° C. (77° F.), except when otherwise indicated. For saccharimeters the temperature is fixed at 20° C. (68° F.) by international agreement.

For calculating the specific rotatory power of an optically active liquid substance, or solution of an optically active solid, the following formulas are of general application:

I. For liquid substances $$[\alpha]_D = \frac{100 \times \alpha}{L \times d}$$

II. For solutions of solids $$[\alpha]_D = \frac{10000 \times \alpha}{L \times p \times d}$$

or $$[\alpha]_D = \frac{10000 \times \alpha}{L \times c}$$

For calculating these formulas the determination of the following factors is necessary:

α = the angle of rotation of the liquid or solid observed with sodium light.

L = the length of the tube in millimeters.

d = the density of the active liquid or solution.

p = the amount of active substance in 100 parts by weight of the solution.

c = the number of grammes of active substance in 100 mils of solution.

22. Refractive Index

(U. S. P. IX)

When a ray of light passes from one transparent substance to another, it is deflected, except when it enters perpendicularly to the surface of contact. The direction of the deviation is dependent upon the difference of density of the two substances; the extent is also influenced by this difference.

This deviation is termed refraction. When the ray passes from a substance of given density to one of greater density (*i.e.*, from air into glass) the refraction is towards the perpendicular meeting the surface at the point of contact; when passing from a substance of greater density to one of less (*i.e.*, from water into air) the ray deviates from the perpendicular at the point of contact.

Quantitative measurements of refraction are expressed as " indices of refraction," the index being the figure obtained by dividing the sine of the angle that the incident ray makes with the perpendicular, by the sine of the angle that the refracted ray makes with the same perpendicular; that is, it is the ratio between these sines. Thus, the ratio for a ray of light passing from air into water at standard temperature is about 4:3 or, expressing it decimally and with greater exactness, 1.336. This is, therefore, the index of refraction of water. The determination of the refractive index is accomplished by means of optical instruments known generally as *refractometers*, which are of several types. Some of these give figures on an arbitrary scale, the actual refractive index being ascertained by consulting a table.

As the exact temperature at which the examination is made is of great importance, all of the instruments are provided with attachments for circulating water of the proper temperature about the prisms or about the vessel containing the liquid to be observed, and are also equipped with thermometers for observing the temperature very closely.

The principal instruments in use are as follows:

Pulfrich Refractometer.—This instrument is used chiefly for purely scientific investigations. It is adapted for use with liquids and solids of all degrees of refractive power. When a liquid is to be examined

it is placed in a small cylindrical glass vessel immediately above the observation prism. When solids are to be examined the glass cylinder is removed and the solid (previously polished) is placed in direct contact with the observation prism. The reading of this instrument is made by noting a boundary line between a light and a dark field in its position with reference to a graduated scale upon which the refractive index is directly expressed.

The Abbe Refractometer.—This is an instrument of wide utility, designed primarily for the examination of liquids. Only a few drops of the liquid are required for an observation. This is spread in a thin film between the two observation prisms. The index of refraction is also read off directly upon the scale of this instrument, in which, as in the Pulfrich Refractometer, a boundary line between a light and a dark field is the observation line.

The Zeiss Butyro-Refractometer.—This instrument is especially designed for the examination of fixed oils and fats. It is not applicable to aqueous or alcoholic liquids. The distinctive line for observation in this instrument is the border line of total reflection which is a narrow line capable usually of being accurately read to within a tenth of a unit of the arbitrary scale used. Sometimes this observation line is accompanied by a blue or a red fringe or haze which interferes with the accuracy of the reading. Should a close reading be impossible on this account it will be found necessary to use the monochromatic sodium flame for the observation (see under optical rotation).

Zeiss Immersion Refractometer.—This is adapted for the examination of aqueous, oily, or alcoholic liquids. The distinctive line for observation is as described under the preceding instrument, the border line of total reflection, which in this case is much sharper and capable of being much more accurately read. For making observations of the entire range of Pharmacopœial substances the Abbe instrument is the one generally selected, the Pulfrich instrument not being in common use and the Zeiss Butyro- and Immersion Refractometers not covering the entire range necessary.

23. Biological Assays

(U. S. P. IX)

Inasmuch as there are several drugs more or less extensively used in the treatment of disease, for which no satisfactory chemical method of assay has been developed, other assays have been introduced in which these drugs are administered to animals and the effects noted. From the results obtained from these assays the strength of the preparation is calculated, and if necessary proper corrections are made so that the preparation shall conform to the standard which has been adopted. The official drugs to which these methods of assay have been applied in the following pages, are the members of the digitalis group, cannabis, and aconite and the suprarenal gland.

Brief descriptions of the more commonly accepted methods are given here in order, first, to direct the attention of manufacturers to them; second, to ascertain the points of weakness which may exist in them; and finally, to outline methods and establish standards which those interested may adopt should they desire to assay their products and have them conform to the standards proposed.

All preparations thus assayed and made to conform to these standards may be labeled " Physiologically assayed and standardized according to the U. S. P. IX."

In the case of Cannabis and its preparations, the biological assay standards are compulsory.

Cannabis

The assay of Cannabis and its preparations has been made a requirement and is based upon the fact that this drug produces certain symptoms of muscular incoördination. The method consists of ascertaining the dose of the preparation to be tested which will produce these symptoms of incoördination in dogs and then adjusting its strength by comparison with a standard preparation.

Dogs.—The animals differ considerably in susceptibility to the drug and therefore it is best to make preliminary tests upon several dogs with average-sized doses and select from among them the animals which react easily to the drug. As a rule, fox terriers serve very well for the purpose, but any dog may prove satisfactory. It is best to provide at least two dogs for each assay but if many samples are to be examined more dogs will be needed. The dogs should be at least one year old and in normal health and must be kept under the best sanitary conditions. They may be used repeatedly for the purpose but not at shorter intervals than three days. Each series of tests should be conducted by the same person, who should be perfectly familiar with the peculiarities of each animal in order that he may recognize more certainly deviations from the normal. While the tests are being made the animals should be kept in a perfectly quiet room free from disturbance and separated so that they cannot see each other.

Preparation of the Drug.—The drug may be given most conveniently in the form of the fluidextract which is administered in gelatin capsules, or the extract made into soft pills may be used; but whichever form is chosen the same should be used for both the standard and the preparation that is to be tested.

Before administration the animal should not be fed for twenty-four hours in order to hasten absorption. The head of the animal being held, its mouth is opened and the capsule or pill is placed upon the back of the tongue. Usually the drug is easily swallowed when given in this way, but this may be facilitated by giving the animal a small amount of water to drink.

Assay.—An average dose of the known or standard preparation is given to one of the dogs and a like dose of the preparation to be standardized is given the second dog. After one hour both dogs are observed very carefully for symptoms of muscular incoördination. The incoördination is manifested differently in different animals, but in small doses it shows itself most frequently in slight swaying, when the animal is standing quietly, or in some ataxia when it runs about. The observation should be made frequently during the second hour following the administration of the drug.

The results obtained from the first test should be confirmed after an interval of not less than three days by repeating the administration but reversing the order, that is, giving the known strength drug to the dog which received that of unknown strength before and *vice versa*.

In subsequent tests which are carried out, the dose of the preparation of unknown strength is modified so as to produce similar symptoms to those produced by the standard. If the preparation to be tested is below the standard in strength, its dose must be increased, or if it is above strength its dose is lessened until equivalent doses of the two are found. Dogs may be used over long periods of time, even for some years, but occasionally they have to be discarded, as in some cases they seem to learn the effects of the drug and so refuse to stand up. A certain degree of tolerance is sometimes gained which necessitates larger doses.

Standard.—As there is no chemical substance of definite composition which can be adopted as a standard, a Fluidextract of Cannabis or an extract which has been carefully prepared and suitably preserved may be utilized for this purpose. A standard Fluidextract will produce incoördination when administered to dogs in the dose of 0.03 mil for each kilogramme of body weight of dog. When administered in the form of the Extract a dose of 0.004 Gm. for each kilogramme of body weight of dog should produce similar symptoms, and the requirement for a standard tincture is a dose of 0.3 mil for each kilogramme of body weight of dog.

Aconite

The method for the physiological assay of Aconite depends upon the determination of the minimum lethal dose for guinea-pigs.

Method.—The guinea-pigs to be utilized should be of average size and not too large; preferably from 250 to 350 Gm. in weight and in healthy condition.

The drug may be administered in the form of fluidextract, extract, or tincture, which in the preliminary trial may be injected subcutaneously into a series of guinea-pigs in doses having sufficiently wide limits. If the extract is to be standardized, it must be dissolved in sufficient solvent to produce a liquid preparation before injection. The animals after injection are placed in cages and at the end of the observation (twelve hours), note is taken of those living and dead.

After this preliminary test, the limits of the doses for a second series of animals are further narrowed and, if necessary to still further confirm the earlier results, additional series may be injected until the minimum lethal dose for the guinea-pig is found.

Standard.—A satisfactory preparation of the Fluidextract of Aconite should kill guinea-pigs when administered in doses of 0.00004 mil for each gramme of body weight of guinea-pig; a satisfactory Tincture of Aconite should prove fatal to guinea-pigs when given in doses of 0.0004 mil for each gramme of body weight of guinea-pig and a satisfactory Extract of Aconite should have a minimum lethal dose not greater than 0.00001 Gm. for each gramme of body weight of guinea-pig.

Digitalis—Strophanthus—Squill

For the members of the digitalis series the so-called " one hour frog " method is recommended. This method consists essentially in ascertaining the dose of a drug or preparation which will bring the heart of a standard sized frog to systolic standstill in one hour's time. The method is carried out as described below; all measurements being performed with the same degree of accuracy used in ordinary quantitative chemical estimations.

Frogs.—The frogs to be employed in an assay should be in a healthy condition and of the same species. Those most commonly obtainable in this country are the common grass frogs (*Rana viridis* or *Rana pipiens*). While the dose for a frog is estimated according to its weight, it is best to use frogs of a fairly uniform size, the most convenient weight for such work being between 15 and 25 Gm.

Storage.—Before use the frogs should be stored in tanks kept in a cool room, preferably where the temperature does not rise above 15° C. (59° F.). The bottom of the tanks should be covered with running water or, if running water is not convenient, standing water may be used if it is changed from two to four times daily. An hour before the frogs are to be used for an assay a sufficient number should be taken to the operating room, each one carefully weighed to within 0.1 Gm. and placed in an individual wire cage or container, these are then placed in a tank containing water to the depth of about 1 cm. (½ inch) which is kept during the process of assay at a uniform temperature of 20° C. (68° F.). The maintaining of a uniform temperature at which all assays of the members of this group should be carried out is important, as the susceptibility of frogs differs very considerably at different temperatures.

Dosage.—After the frogs have been weighed as described, the doses to be given are calculated according to their weights and are measured into small conical glasses by means of a finely graduated pipette. The doses of the preparation which are to be injected should be as uniform in quantity as possible and should not exceed 0.015 mil for each gramme of body weight of frog. The members of the digitalis series may be assayed in either fluidextract or tincture strength, being diluted with water as may be necessary to get the volume dose. In case the alcohol content in any preparation after dilution is higher than 20 per cent., the preparation may be subjected to careful evaporation and subsequent dilution with an aqueous solution containing 0.7 per cent. of sodium chloride until the original volume is restored and the alcohol content is not above the per cent. named. It is always best to have the alcohol content of different preparations uniform. In case there is a precipitate the preparation to be assayed should be shaken each time a dose is measured out.

When the doses are ready, they may be injected into the anterior lymph sac of the animal. This is done by means of a glass pipette which is drawn out to a fine point. The frog is held on its back in one hand and the pipette with the contained drug in the other, the mouth of the frog is opened with the point of the pipette and, carefully avoiding the tongue, the floor of the mouth is punctured and the point of the pipette is then seen to enter the anterior lymph sac of the frog. The contents of the pipette are now forced into the sac either by gravity or by gently blowing, if necessary. In the latter case, care should be taken not to introduce air into the sac. Care should also be taken not to puncture the skin. The animal is then replaced in its cage in the tank, the temperature of which is maintained as stated at 20° C. (68° F.).

At the end of one hour from the time of injection each frog is pithed, both brain and cord, the heart is exposed and its condition examined. For the correct end reaction the ventricle should be in systolic standstill while the auricles should be widely dilated.

Following mechanical stimulation feeble contractions may be allowed in the auricles and localized contractions in the ventricle, but no general contraction is allowable.

If when the heart of an animal is being exposed for examination, remains of the injected drug are found in the lymph sac unabsorbed, such an animal should be discarded and not considered in the results obtained.

It happens sometimes that one frog out of a large series may prove a decided exception to the others in the way of increased or decreased susceptibility to the drug. Such an animal should also be discarded.

After the primary or trial assay has been carried out and the approximate strength of the preparation ascertained, a second series of frogs is injected in like manner, using doses the limits of which are considerably narrower than the first series. A third or even fourth series of injections may be necessary to confirm the earlier results. The dose thus found is then compared with the dose of a standard which is similarly ascertained upon another series of frogs of the same lot. From such a comparison the strength of the unknown preparation can be suitably adjusted.

The use of a standard is made necessary by the fact that frogs differ in their susceptibility to the members of the digitalis series at different seasons of the year. The condition of susceptibility is ascertained and allowed for by the use of a solution of ouabain (see page 1686) as a standard which in appropriate doses is injected into a series of frogs and their resistance thus determined. The necessary strength of an unknown preparation may be calculated from the dose actually found by the ratio of the standard dose of ouabain to the dose of ouabain found necessary to kill. Thus:

Standard dose of ouabain	:	Found dose of ouabain	::	Standard dose of drug being assayed	:	Necessary dose of unknown

The standard dose of ouabain is 0.0000005 Gm. per gramme of body weight of frog.

The standard dose of Tincture of Digitalis to correspond is 0.006 mil per gramme of body weight of frog.

If, therefore, in a certain series of frogs the resistance to ouabain is found to be increased so that a dose of 0.00000075 Gm. is necessary to stop the heart in systole in one hour, the dose of Tincture of Digitalis would also have to be increased to 0.009 mil, and the actual dose found calculated against this, instead of against the standard dose of 0.006 mil. For example, in frogs showing the increased resistance as indicated above, if the Tincture being examined assays 0.018 mil per gramme of body weight it is one-half strength.

Standards.—The standards adopted are as follows: Ouabain, 0.0000005 Gm. (or mil) for each gramme of body weight of frog; digitalis: leaves (in the form of tincture), 0.0006 Gm.; fluidextract, 0.0006 Gm.; tincture, 0.006; strophanthus: seed (in the form of tincture), 0.000006; tincture, 0.00006; squill: dried squill (in the form of tincture), 0.0006; fluidextract, 0.0006; tincture, 0.006.

Suprarenal Gland

The assay of products of the Suprarenal Gland is carried out by means of a comparison of the rise in blood-pressure produced in a dog by an injection of an aqueous preparation of the gland with that produced by a solution of known strength of lævo-methylamino-ethanol-catechol ($C_9H_{13}NO_3$) (see page 1683).

Standard Solution.—Prepare an aqueous solution of lævo-methylamino-ethanol-catechol (1 in 1000), using sufficient diluted hydrochloric acid, and from this solution prepare a second solution of the strength of 1 in 100,000 by adding 1 mil of the original solution (1 in 1000) to 99 mils of physiological solution of sodium chloride; this latter solution should be freshly prepared for each assay.

Prepare a solution by adding 1 Gm. of the finely powdered dried suprarenal glands to be tested to 100 mils of distilled water containing 10 mils of diluted hydrochloric acid, allow this mixture to macerate during twenty-four hours, shaking it frequently during that time, and then filter through a dry filter. It is then ready for use.

Dogs.—The animal, which should be of medium size, is anesthetized with a suitable anesthetic. The animal is prepared for blood-pressure estimations in the usual manner by the insertion of a suitable cannula into one carotid artery and this in turn is connected with an ordinary mercury manometer. The trachea is exposed and a cannula inserted into it so that the animal may receive artificial respiration during the course of the experiment.

The femoral vein on each side is exposed and a cannula inserted in each. These should be fitted with short pieces of small rubber tubing to serve as connections for the injecting syringes.

Two glass syringes graduated to 0.05 mil should be provided, one to be used for injecting the standard and the other for the aqueous preparation of the gland.

Before the test is made, in case any muscular movement such as twitching is present, the dog should receive by intravenous injection, a sufficient dose of curare (see page 1680), but if the animal is deeply anesthetized, this may not be necessary. The dog should also receive a sufficient dose of atropine sulphate (0.001 to 0.002 Gm.) to paralyze the vagi, this paralysis being proved by electrical stimulation.

The blood-pressure tracing may be best taken on a long kymograph, which may be allowed to run from the time of injection until after the crest of the pressure rise has been passed, when it may be stopped.

Injections should be made at regular intervals and these intervals should not be shorter than five minutes.

One cannula and one syringe are now filled with the standard solution prepared as directed above and 1 mil is injected. The rise of blood-pressure should be submaximal, say from 30 to 60 mm., and in case this figure is much exceeded a second injection of 0.5 mil may be made five minutes later. After a satisfactory dose has been ascertained, 1 mil of the aqueous preparation of the gland may be injected with the second syringe into the femoral vein of the opposite side. In subsequent injections this dose may be increased or decreased as necessary until such an amount is found as will give the same elevation of blood-pressure as the established dose of the standard solution when the two solutions are given in alternating doses. When this relation has been ascertained, it should be confirmed on the same animal by making the injection into the opposite sides from which they have been made in the earlier tests. Before these confirmatory tests are made, it is necessary to wash out the cannulas most carefully before the new solutions are introduced.

The ratio of activity found between these two solutions may be confirmed by injections made into a second animal, using a new aqueous extract of the gland prepared in the same manner as the first.

From the results thus obtained, the strength of the aqueous preparation of the gland may be determined by calculation and expressed in terms which indicate its relative activity as compared with that of the standard.

Standard.—One gramme of *Suprarenalum Siccum* contains the equivalent of 10 milligrammes of lævo-methylamino-ethanol-catechol.

Standard Thermometers

(U. S. P. IX)

General Requirements.—The bulbs are to be of Jena 16 III normal glass or Corning normal thermometer glass. The stems may be made of other white enamel back glass tubing having a circular cross section; the diameter of the capillary must not be greater than 0.1 mm. The diameter of the stem is to be 5.5 mm. (to within ± 0.3 mm.), and the maximum diameter of the bulb must not be greater than the diameter of the stem. The thermometers are to have a pear-shaped reservoir, at the upper end of the capillary having a volume at least equal to the volume of the entire graduated portion of the stem. The upper end of the stem is to have a small glass ring.

Graduation.—The thermometers are all to be graduated into 0.5° (one-half degree) intervals. The 1° graduation marks are to be longer than those for the half degrees, the longer graduations extending, preferably, equally to the right and left of the shorter marks. The graduation marks are to be clean cut and fine, and to be uniformly well-filled with insoluble colored pigment.

Numbering.—The 100° graduations (the 0°, 100°, 200°, 300° graduations on the different thermometers) are to be numbered in full and the intermediate 5° and 10° graduations are to be numbered 5, 10, 15, etc. . . . 95, 100, 5, 10, 15, . . . 95, 200, 5, 10, etc. The numbers must be distinct and easily legible and preferably in such position that they will be upright when the thermometer is vertical. The figures should not be unduly large. It is suggested that the figures opposite the 0°, 100°, 200°, 300° graduations be made about 2 mm. in height and the intermediate numbers 5, 10, 15, etc., somewhat less (about 1.4 mm.).

Annealing.—The thermometers should be so thoroughly annealed that there will be no appreciable change in their indications after long continued exposure to the highest temperature on the scale.

Error of Scale.—The maximum error at any temperature below 100° C. must not exceed 0.5°, nor exceed 1.0° in the interval 100° to 350° C.

Standardization.—The thermometers should be submitted to the Bureau of Standards for standardization or carefully compared with thermometers actually standardized by the Bureau of Standards.

Filling Under Pressure.—Thermometers reading over 200° C. must be filled under sufficient pressure to prevent the mercury column from boiling or breaking up into small pieces.

Thermometer No. 1.—The thermometer is to be graduated from −10.5° to 125.5° C. into half degrees, the length of a 1° interval being 1.5 to 2 mm.

Thermometer No. 2.—The thermometer is to be graduated from 98° to 225.5° C. into half degrees, the length of a 1° interval being 1.5 to 2 mm. The graduations to begin a short distance above top of bulb so that the distance from first graduation (98°) to bottom end of bulb shall not be over 40 mm.

Thermometer No. 2A.—The thermometer is to be graduated into half degrees in the neighborhood of ice point from 1° to 2°, above which is to be a small enlargement in the capillary, and then a graduated portion extending from 98° to 250.5° C., the length of a 1° interval being 1.5 to 2 mm. The length of the thermometer between the 98° mark and the lower end of the main bulb should not exceed 65 mm.

Thermometer No. 3.—The thermometer is to be graduated from 198° to 350.5° C. into half degrees, the length of a 1° interval being 1.5 to 2 mm. The graduations to begin a short distance above the top of the bulb so that the distance from the first graduation (198°) to the bottom end of the bulb shall not be over 40 mm. The graduated stem to be the same length as Nos. 1 and 2.

Thermometer No. 3A.—The thermometer is to be graduated into half degrees in the neighborhood of the ice point from −1° to 4°, above which is to be a small enlargement in the capillary, and then a graduated portion extending from 198° to 350.5° C., the length of a 1° interval being 1.5 to 2 mm. The length of the thermometer between the 198° mark and the lower end of the main bulb should not exceed 65 mm.

Auxiliary Thermometer.—This thermometer is for emergent stem corrections. Use a standard thermometer from 15 to 20 cm. in length and graduated from 20° to 100° C., into degrees.

Thermometers for Boiling Points.—In order to avoid the necessity of an emergent stem correction, it is advisable that an accurately standardized thermometer of the Anschütz type be used for boiling points. If such a thermometer is not available, a thermometer such as is specified above (see No. 1, 2, or 3) may be employed, applying the emergent stem correction as described under *Melting Points* (see page 1716), the length of emergent stem being measured, in degrees, from the lower end of the stopper to the highest point of the boiling temperature.

Sterilization

(U. S. P. IX)

The term "Sterilization" as employed in the practice of medicine and pharmacy means the destruction or removal of bacteria or their spores and other living organisms. This may be accomplished in various ways, depending upon the nature of the material to be sterilized.

A sterile condition can be maintained only so long as the substance or material is kept from contact with air or other media which may carry micro-organisms.

The important subject of sterilization cannot be treated with any great degree of particularity, nor can the intricate details of scientific technique be fully described in this Chapter.

Glass and Metal Utensils.—These may be sterilized by heating them from 160° to 170° C. (320° to 338° F.) for two hours in a hot-air sterilizing oven, or in a closed vessel (autoclave) under steam pressure at a temperature of from 115° to 120° C. (239° to 248° F.) for fifteen minutes. Heating in a current of steam for

thirty minutes, or thoroughly boiling for fifteen minutes in water, or in an aqueous solution of sodium bicarbonate (1 in 1000) will kill all nonspore-bearing organisms and some spore-bearing organisms. As the presence of even a minute quantity of alkali is objectionable in glass containers in certain cases, the process of sterilization should in such instances be preceded by a thorough cleansing of the bottle, ampul or other receptacle with dilute hydrochloric acid, 1 per cent., followed by a thorough rinsing with distilled water.

Stoppers.—Rubber stoppers only should be used for containers and these should be sterilized before use. Cork stoppers should not be used.

Medicinal Solutions Not Easily Decomposed by Heat.—Solutions which are not injured by high temperatures should be sterilized in a current of steam, in an oven, or in a closed apparatus (autoclave) by steam under pressure.

Sterilization in a current of steam should not be concluded in less than thirty minutes and the heat should preferably be continued for one hour; an exposure of from fifteen to twenty minutes is sufficient if the sterilization is carried out in a pressure apparatus at a temperature of from 115° to 120° C. (239° to 248° F.).

Wrap the utensils or containers in parchment paper before starting sterilization for protection against contamination and do not remove the paper until the solution is to be used.

Medicinal Solutions of Substances Readily Decomposed by Heat.—Solutions of substances which are decomposed when subjected to the heat and manipulation directed in the preceding paragraph (this includes solutions of many alkaloids) may be prepared in an approximately sterile condition as directed below:

Method 1.—Filter the solution through a stone or porcelain filter which has previously been tested to prove its efficiency in removing bacteria.

Method 2.—Sterilize all utensils necessary for weighing, such as scales, spatulas, etc., either in steam or, immediately before use, by a thorough cleansing, first with purified cotton saturated with alcohol, then with cotton saturated with ether. Then dissolve the substance in a sterilized, glass-stoppered container, holding the required amount of sterilized distilled water. Should the solution require filtration, use a sterilized funnel and filter paper and collect the filtrate in a sterilized container, closing it with a sterilized rubber stopper. The filtration must be conducted in such a manner that no contamination will result.

Emulsions in Glycerin or Oil.—Approximately sterile solutions or emulsions in glycerin or oil may be prepared in the following manner: heat glycerin in a steam sterilizer as described under *Medicinal Solutions Not Easily Decomposed by Heat*, or heat oil for two hours in a dry-air sterilizer at about 120° C. (248° F.), then introduce the medicinal substances after the liquid has cooled. The desired medicament may be incorporated by triturating it in a sterilized mortar containing the previously sterilized medium (glycerin or oil), and the solution or emulsion should then be quickly transferred to a sterilized glass container.

When solutions have been passed through carefully tested porcelain filters and properly collected and kept in sterile containers, they may be considered "sterile."

Surgical Dressings.—Cotton, bandages, gauzes, ligatures, etc., may be rendered sterile by treatment with steam in a pressure apparatus (autoclave) at 115° C. (239° F.) for fifteen minutes or by exposure to dry heat in an ordinary air-bath or sterilizer at a temperature of from 160° to 170° C. (320° to 338° F.) for two hours. It should be remembered that all surgical materials are not amenable to such thorough treatment without more or less deterioration taking place. Bandages must be folded or packed in such a manner as to permit the penetration of steam or dry heat during the process and should be so arranged that after the sterilization is completed all subsequent contamination with bacteria will be prevented. This is usually accomplished by immediately enclosing them in glass containers or wrapping them in a number of thicknesses of previously sterilized parchment paper.

Diagnostical Reagents and Clinical Tests

(U. S. P. IX)

In the following pages of Diagnostical Reagents and Clinical Tests it is understood that the standard for official substances like Iodine, Potassium Iodide, Gelatin, Sodium Chloride, etc., are those to be found in the text of this Pharmacopœia. Where other substances not described in Part I are used a description will be found among the reagents (see pages 1675 to 1692). If the solutions are not clear filter them.

Reagents for Examination of Urine

For Acetone Reaction

Sodium Nitroprusside (see page 1690, used for Legal's test and Lange's test).

Iodine Potassium Iodide Solution (for Lieben's solution): Potassium Iodide, 6 Gm.; Iodine, 4 Gm.; Distilled Water, a sufficient quantity to make 100 mils. Dissolve the potassium iodide in the distilled water, add the iodine and shake the mixture frequently until a solution is obtained.

Alcoholic Solution of Iodine (10 per cent.), for Gunning's reaction. To be freshly prepared.

For Albumin Reaction

Glacial Acetic Acid (see page 13).

Acetic Acid (see page 13).

Potassium Ferrocyanide (see page 1688).

Nitric Acid (see page 45).

Saturated Aqueous Solution of Trinitrophenol (see page 1164).

Esbach's Reagent: Trinitrophenol, 1 Gm.; Citric Acid, 2 Gm.; Distilled Water, a sufficient quantity, to make a solution measuring 100 mils.

Spiegler-Jolles' Reagent: Corrosive Mercuric Chloride, 2 Gm.; Succinic Acid, 4 Gm.; Sodium Chloride,

4 Gm.; Distilled Water, a sufficient quantity, to make 100 mils. Mix the several ingredients and dissolve them in the distilled water.

Trichloracetic Acid (see page 81).

For Albumose Reaction

Phosphotungstic Acid (see page 1687) (Salkowski's test).

For Bile Reactions

UROBILIN

Amyl Alcohol (see page 1677).

Solution of Zinc Chloride (about 10 per cent.): Zinc Chloride, 10 Gm.; Distilled Water, a sufficient quantity to make a solution measuring 100 mils.

Mixture of Zinc Acetate: Zinc Acetate, 10 Gm.; Dehydrated Alcohol, a sufficient quantity to make 100 mils. Finely powder the zinc acetate and intimately mix it with the alcohol. Dispense the mixture with directions "to be well shaken before using."

UROBILINOGEN

Ehrlich's Solution: Paradimethylamidobenzaldehyde, 2 Gm.; Hydrochloric Acid, 50 mils; Distilled Water, a sufficient quantity to make a solution measuring 100 mils.

BILIARY COLOR REACTIONS

Nitric Acid (containing a trace of nitrous acid).

Solution of Calcium Chloride (about 10 per cent.) (Hupert's reaction): Calcium Chloride, 10 Gm.; Distilled Water, a sufficient quantity to make a solution measuring 100 mils.

Alcoholic Solution of Iodine (about 1 per cent.): Iodine, 1 Gm.; Alcohol, a sufficient quantity to make a solution measuring 100 mils.

For Blood Reaction

Solution of Guaiac: Guaiac, 2 Gm.; Dehydrated Alcohol, a sufficient quantity to make a solution measuring 100 mils.

Oxygenated Oil of Turpentine.

Ether containing Hydrogen Dioxide.

Aloin, isobarbaloin containing barbaloin.

For Diacetic Acid Reaction

Solution of Ferric Chloride (see page 633) used for Gerhardt's test.

For Diazo Reaction, Ehrlich

1. Sodium Nitrite, 1 Gm.; Distilled Water, a sufficient quantity to make 200 mils.

2. Sulphanilic Acid, 5 Gm.; Hydrochloric Acid, 50 mils; Distilled Water, a sufficient quantity to make 1000 mils. Dissolve the sulphanilic acid in about 700 mils of distilled water to which the hydrochloric acid has been added and follow with enough distilled water to make the product measure 1000 mils. For use, 1 mil of the sodium nitrite solution should be mixed with 50 mils of the sulphanilic acid solution.

For Indican Reactions

Solution of Chlorinated Lime:

A saturated solution of chlorinated lime diluted with an equal volume of distilled water and filtered.

Obermeyer's Solution: Ferric Chloride, 0.4 Gm.; Hydrochloric Acid, a sufficient quantity to make a solution measuring 100 mils.

Solution of Lead Acetate: Lead Acetate, 25 Gm.; Distilled Water, a sufficient quantity to make a solution measuring 100 mils.

For Pentose Reactions

Bial's Reagent: Orcin, 1 Gm.; Hydrochloric Acid, 500 mils; Solution of Ferric Chloride, 25 drops. Dissolve the orcin in the hydrochloric acid and add the solution of ferric chloride.

Phloroglucinol (see page 1686).

For the Estimation of Urea

Solution of Sodium Hypobromite: 1. Bromine, 125 Gm.; Sodium Bromide, 125 Gm.; Distilled Water, a sufficient quantity to make a solution measuring 1000 mils.

2. Sodium Hydroxide, 225 Gm.; Distilled Water, a sufficient quantity to make a solution measuring 1000 mils. The reagent should be freshly prepared by mixing equal volumes of solutions 1 and 2 and diluting the resulting mixture with one and a half volumes of distilled water.

For Sugar Reactions

Solution of Sodium Hydroxide: Sodium Hydroxide, 10 Gm.; Distilled Water, a sufficient quantity to make a solution measuring 100 mils.

Solution of Copper Sulphate: Copper Sulphate, 10 Gm.; Distilled Water, a sufficient quantity to make a solution measuring 100 mils.

Nylander's Reagent: Potassium and Sodium Tartrate, 4 Gm.; Sodium Hydroxide, 10 Gm.; Bismuth Subnitrate, 2 Gm.; Distilled Water, a sufficient quantity to make 100 mils.

Dissolve the potassium and sodium tartrate in 90 mils of distilled water. Add the bismuth subnitrate to the solution, shake the mixture thoroughly and then filter through glass wool. Preserve and dispense this solution in amber-colored bottles.

Fehling's Solution (see Alkaline Cupric Tartrate V.S., page 1694).

Pavy's Solution: 1. Copper Sulphate, 4.158 Gm.; Distilled Water, a sufficient quantity to make a solution measuring 500 mils.

2. Potassium and Sodium Tartrate, 20.4 Gm.; Potassium Hydroxide, 20.4 Gm.; Stronger Ammonia Water, 300.0 mils; Distilled Water, a sufficient quantity to make a solution measuring 500 mils. For use, mix equal quantities of the two solutions.

Phenylhydrazine Hydrochloride (see page 1686).

Sodium Acetate: Neutral to litmus paper.

Fermentation test with yeast.

Reagents for the Examination of Gastric Contents

Congo Red Test Paper:

Saturate filter paper with an aqueous solution of Congo Red (1 in 1000), page 1707. Dry and cut the paper into strips and preserve them in well-stoppered glass vials.

Saturated Alcoholic Solution of Methylthionine Chloride (*Methylene Blue*) (see page 697).

Alcoholic Solution of Dimethylaminoazobenzene (see page 1680) (1 in 200).

Günzburg's Reagent: Phloroglucinol, 2 Gm.; Vanillin, 1 Gm.; Alcohol, 30 mils. Dissolve the ingredients in the alcohol.

Tenth-normal Hydrochloric Acid V.S. (see page 1696): Dilute 1 volume of normal hydrochloric acid V.S. with exactly 9 volumes of distilled water.

Tenth-normal Potassium Hydroxide V.S. (see page 1699).

Phenolphthalein (see page 843).

Solution of Rosolic Acid: Rosolic Acid, 1 Gm.; Alcohol, a sufficient quantity to make a solution measuring 100 mils.

Carminfibrin: Heat freshly-drawn beef blood, wash the stringy coagulated fibrin in running water until decolorized, cut the fibrin into small pieces of uniform size and macerate it in alcohol for several days. Then transfer the fibrin for one or two days to a 0.5 per cent. ammoniacal solution of carmine, which contains as little excess of ammonia as possible, and keep it cool until the fibrin is thoroughly stained. Wash the product in distilled water until the wash-water is no longer colored, squeeze it out well, and then preserve it in glycerin. Before using, carefully wash the carminfibrin in distilled water to free it from glycerin.

Reagents for the Examination of Blood

For red blood-corpuscles:

Hayem's Solution: Sodium Sulphate, 5 Gm.; Sodium Chloride, 1 Gm.; Corrosive Mercuric Chloride, 0.5 Gm.; Distilled Water, 200.0 mils. Dissolve the salts in the distilled water and filter.

Toison's Solution: Methyl Violet 6B, 0.025 Gm.; Sodium Chloride, 1.000 Gm.; Sodium Sulphate, 8.000 Gm.; Glycerin, 30.000 mils; Distilled Water, 300.000 mils. Dissolve the salts in the distilled water and add the methyl violet and the glycerin.

For white corpuscles: Acetic Acid (U.S.P.), 1 mil; Distilled Water, 99 mils; mix them.

Solution for Hemoglobin Estimation (*Sahli's hemometer*): Tenth-normal hydrochloric acid V.S. saturated with chloroform. This solution should always be freshly prepared and be dispensed in dark amber-colored bottles.

Jenner's Stain: 1. Eosin, 0.5 Gm.; Methyl Alcohol, rectified wood alcohol, sp. gr. about 0.812 at 25° C. (77° F.), a sufficient quantity to make a solution measuring 100 mils.

2. Methylthionine Chloride (Methylene Blue), 0.5 Gm.; Methyl Alcohol, rectified wood alcohol, sp. gr. about 0.812 at 25° C. (77° F.), a sufficient quantity to make a solution measuring 100 mils. For use mix 25 mils of eosin solution with 20 mils of methylene blue solution.

Ehrlich's Triacid Stain: Saturated Aqueous Solution of Orange-G, 120 to 125 mils; Saturated Aqueous Solution of Acid Fuchsin, 80 to 165 mils; Saturated Aqueous Solution of Methylene Green, 125 mils; Distilled Water, 300 mils; Dehydrated Alcohol, 200 mils; Glycerin, 100 mils; mix.

Wright's Stain: Wright's Stain (Grübler's dried powder), 0.1 Gm.; Methyl Alcohol, rectified wood alcohol, sp. gr. about 0.812 at 25° C. (77° F.), 60.0 mils.

Giemsa's Stain: Azur II-Eosin, 0.3 Gm.; Azur II, 0.8 Gm.; Glycerin, 250.0 mils; Methyl Alcohol, rectified wood alcohol, sp. gr. about 0.812 at 25° C. (77° F.), 250.0 mils. Dissolve the dyes in the methyl alcohol and add the glycerin and filter.

Stains and Accessories for use in connection with the study of Micro-organisms

Alum-hematoxylin Solution: Hematoxylin, crystals, 1.0 Gm.; Saturated Aqueous Solution of Ammonium Alum, 100.0 mils; Distilled Water, 300.0 mils; Thymol, 0.5 Gm. Dissolve the hematoxylin in a little distilled water by the aid of heat, add the other ingredients and expose the combined solution to the light, in a bottle loosely stoppered, until it has assumed a dark red color, then filter. The thymol is added as a preservative.

Mayer's Hemalum: Hematein or its ammonium salt, 1.0 Gm.; Alcohol, 90 per cent., 50.0 mils; Alum, 50.0 Gm.; Distilled Water, 1000.0 mils; Thymol, 0.5 Gm. Dissolve the hematein in the alcohol by the aid of heat, add the thymol, and then this solution to the alum dissolved in the distilled water, and then filter. The thymol is added as a preservative.

Alcoholic Solution of Methyl Violet 6B: Methyl Violet 6B, 10 Gm.; Alcohol, a sufficient quantity to make a solution measuring 100 mils.

Borax-Methylene Blue Solution: Methylthionine Chloride (Methylene Blue), 2 Gm.; Boiling Solution of Sodium Borate (1 in 20) a sufficient quantity to make a solution measuring 100 mils.

Löffler's Methylene Blue Solution: Methylthionine Chloride (Methylene Blue), 0.5 Gm.; Alcohol, 30.0 mils; Tenth-normal Potassium Hydroxide V.S., 2.0 mils; Distilled Water, 98.0 mils. Dissolve the methylene blue in the alcohol, add the potassium hydroxide and distilled water.

Solution of Carbol Methyl Violet: Alcoholic Solution of Methyl Violet 6B, 10 mils; Aqueous Solution of Phenol (1 in 20), a sufficient quantity to make a solution measuring 100 mils.

Solution of Carbolfuchsin: Alcoholic Solution of Fuchsin (1 in 10), 10 mils; Aqueous Solution of Phenol (1 in 20), 100 mils; mix.

For Tubercle Bacilli

Solution of Carbolfuchsin (see above).

For Decolorizing

Ebner's Fluid: Hydrochloric Acid, 2.5 mils; Sodium Chloride, 2.5 Gm.; Distilled Water, 100.0 mils; Alcohol, 500.0 mils. Prepare a solution.

Nitric Acid Solution: Nitric Acid, 30 mils; Distilled Water, a sufficient quantity to make a solution measuring 100 mils.

Diluted Alcohol.

Diluted Lugol's Solution (Gram's Iodine Solution): Iodine, 1 Gm.; Potassium Iodide, 2 Gm.; Distilled Water, a sufficient quantity to make a solution measuring 200 mils.

For Counter Staining

Löffler's Methylene Blue Solution (see above).

Gram's Stain (Aniline Water—Methyl Violet 6B Solution): Aniline, 15 mils; Saturated Alcoholic Solution of Methyl Violet 6B, 7 mils; Dehydrated Alcohol, 10 mils; Distilled Water, a sufficient quantity to make 100 mils. Shake the aniline with 65 mils of distilled water for several minutes; filter the resulting opalescent aniline water through a moistened filter, pour the filtrate into a solution prepared by mixing the other liquids and add sufficient distilled water to make 100 mils.

Diluted Carbolfuchsin Solution: Solution of Carbolfuchsin (see above), 1 mil; Distilled Water, 4 mils. Prepare a solution.

Accessories

Xylene (see page 1692).
Oil of Clove (see page 756).
Oil of Cedarwood (see page 1685).
Canada Turpentine (Canada Balsam) (see page 1679).

Culture Media

Bouillon Stock: Lean Beef, 500 Gm.; Or Extract of Beef, 3 Gm.; Distilled Water, a sufficient quantity to make 1000 mils. Mix thoroughly 500 Gm. of finely minced lean beef with 1000 mils of cold distilled water, heat it to boiling in a closely covered dish or flask and keep it at that temperature for one hour. If extract of beef is used to make bouillon stock, boil the solution for one-half hour. Filter the resulting bouillon through a well-wetted filter, until clear and use it as the basis for the following combinations:

Plain Bouillon: Peptone, 10 Gm.; Sodium Chloride, 5 Gm.; Normal Sodium Hydroxide V.S.; Bouillon Stock, each a sufficient quantity to make 1000 mils. Dissolve the peptone and sodium chloride in the bouillon stock by means of heat and add sufficient normal sodium hydroxide V.S. to make the mixture neutral to litmus. Then filter the product through a well-wetted filter, fill it into suitable containers and sterilize.

Glucose Bouillon: Glucose (dry), 10 Gm.; Peptone, 10 Gm.; Sodium Chloride, 5 Gm.; Normal Sodium Hydroxide V.S.; Bouillon Stock, each, a sufficient quantity to make 1000 mils. Dissolve the glucose, peptone, and sodium chloride in the bouillon stock by means of heat and add sufficient normal sodium hydroxide V.S. to neutralize the resulting solution. Then filter the product through a well-wetted filter, fill it into suitable containers and sterilize by the discontinuous method.

Plain Gelatin: Gelatin, 100 Gm.; Peptone, 10 Gm.; Sodium Chloride, 5 Gm.; Normal Sodium Hydroxide V.S.; Bouillon Stock, each, a sufficient quantity to make 1000 mils. Dissolve the gelatin, peptone, and sodium chloride in the bouillon stock by means of heat and add sufficient normal sodium hydroxide V.S. to neutralize the resulting mixture. Filter the warmed product through filter paper, fill it into suitable containers and sterilize by the discontinuous method.

Glucose Gelatin: Glucose (dry), 10 Gm.; Gelatin, 100 Gm.; Peptone, 10 Gm.; Sodium Chloride, 5 Gm.; Normal Sodium Hydroxide V.S.; Bouillon Stock, each, a sufficient quantity to make 1000 mils. Dissolve the glucose, gelatin, peptone, and sodium chloride in the bouillon stock by means of heat and add sufficient normal sodium hydroxide V.S. to neutralize the resulting mixture. Then filter the product through paper, fill it into suitable containers and sterilize by the discontinuous method.

Plain Agar-agar: Agar, 15 Gm.; Peptone, 10 Gm.; Sodium Chloride, 5 Gm.; Normal Sodium Hydroxide V.S.; Bouillon Stock, each, a sufficient quantity to make 1000 mils. Dissolve the agar, peptone, and sodium chloride in the bouillon stock by means of heat and add a sufficient quantity of normal sodium hydroxide

V.S. to neutralize the resulting mixture. Then filter the warmed product through paper, fill it into suitable containers and sterilize.

Glucose Agar-agar: Glucose (dry), 10 Gm.; Agar, 15 Gm.; Peptone, 10 Gm.; Sodium Chloride, 5 Gm.; Normal Sodium Hydroxide V.S., Bouillon Stock, each, a sufficient quantity to make 1000 mils. Dissolve the glucose, peptone, and sodium chloride in the bouillon stock by means of heat, and add a sufficient quantity of normal sodium hydroxide V.S. to neutralize the resulting mixture. Then filter the warmed product through paper, fill it into suitable containers and sterilize by the discontinuous method.

Glycerin Agar-agar: Glycerin, 60 mils; Agar, 15 Gm.; Peptone, 10 Gm.; Sodium Chloride, 5 Gm.; Normal Sodium Hydroxide V.S.; Bouillon Stock, each, a sufficient quantity to make 1000 mils. Dissolve the glycerin, agar, peptone, and sodium chloride in the bouillon stock by means of heat and add a sufficient quantity of normal sodium hydroxide V.S. to neutralize the resulting mixture. Then filter the warmed product through paper to fill it into suitable containers and sterilize.

Lactose-litmus Agar-agar: Sugar of Milk, 10 Gm.; Agar, 15 Gm.; Peptone, 10 Gm.; Sodium Chloride, 15 Gm.; Normal Sodium Hydroxide V.S.; Azolitmin Test Solution (see page 1707); Bouillon Stock, each, a sufficient quantity to make 1000 mils. Dissolve the sugar of milk, agar, peptone, and sodium chloride in the bouillon stock by means of heat and add a sufficient quantity of normal sodium hydroxide V.S. to neutralize the resulting mixture. Then filter the warmed product through paper, add a sufficient quantity of azolitmin solution to impart to the resulting mixture a pale blue color, fill into suitable containers and sterilize by the discontinuous method.

Blood Serum (Löffler's Mixture): Glucose Bouillon, 250 mils; Horse or Beef Blood Serum, 750 mils. Run the mixture of glucose bouillon and beef or horse blood serum into properly sterilized test tubes, and coagulate it by means of heat so as to form a slanting surface for culture purposes.

Articles Employed in Chemical Testing and Reagents of the British Pharmacopœia

APPENDIX I. Br.

The British test-solutions here given are used for determining the character of particular substances, whether isolated or in composition; thus enabling us to ascertain the identity of medicines, their purity or impurity, and the character of the foreign ingredients, which may be mixed with them accidentally, or with a view to adulteration.

Acetic Acid.—"Acetic Acid of the British Pharmacopœia." *Br.*

Acetic Acid, Diluted.—"Diluted Acetic Acid of the British Pharmacopœia." *Br.*

Acetic Acid, Glacial.—"Glacial Acetic Acid of the British Pharmacopœia." *Br.*

Acetic Anhydride.—"Acetic Anhydride $C_4H_6O_3$ of commerce, pure." *Br.*

Acetone.—"Acetone of the British Pharmacopœia." *Br.*

Albumen.—"Albumen, the liquid white of fresh eggs." *Br.*

Alcohol, Absolute.—"Absolute Alcohol of the British Pharmacopœia." *Br.*

Alcohol (90 per cent.). **Alcohol** (70 per cent.). **Alcohol** (20 per cent.).—"Alcohol (90 per cent.), Alcohol (70 per cent.) and Alcohol (20 per cent.) of the British Pharmacopœia." *Br.*

Alum, Purified.—"Purified Alum of the British Pharmacopœia." *Br.*

Ammonium Chloride.—"Ammonium Chloride of the British Pharmacopœia." *Br.*

Ammonium Molybdate.—"Ammonium Molybdate $(NH_4)_2MoO_4$, of commerce, pure." *Br.*

Ammonium Oxalate.—"Ammonium Oxalate $(NH_4)_2C_2O_4,H_2O$, of commerce, pure." *Br.*

Ammonium Persulphate.—"Ammonium Persulphate, NH_4SO_4, of commerce, pure." *Br.*

Ammonium Thiocyanate.—"Ammonium Thiocyanate, NH_4SCN, of commerce, pure." *Br.*

Amylic Alcohol.—"Amylic Alcohol is a liquid consisting principally of iso-primary amylic alcohol, $C_5H_{11}OH$, and may be prepared by shaking commercial fusel oil with a saturated solution of common salt, separating the oily layer, submitting it to distillation, and collecting and reserving the fraction which distils between 125° and 143° C. (257° and 289.4° F.).

Aniline.—"Aniline of commerce, redistilled." *Br.*

Animal Charcoal.—"Animal Charcoal of commerce, purified." *Br.*

Auric Chloride.—"Auric Chloride of commerce, pure." *Br.*

Barium Chloride.—"Barium Chloride, $BaCl_2,2H_2O$, of commerce, pure." *Br.*

Barium Hydroxide.—"Barium Hydroxide, $Ba(OH)_2,8H_2O$ of commerce, pure." *Br.*

Benzene.—"Benzene of the British Pharmacopœia." *Br.*

Benzolated Amylic Alcohol.—"Benzene, 3 parts by volume; Amylic Alcohol, 1 part by volume; mix; decant from any deposited water." *Br.*

Bismuth Oxynitrate.—"Bismuth Oxynitrate of the British Pharmacopœia." *Br.*

Borax, Purified.—"Purified Borax of the British Pharmacopœia." *Br.*

Bromine.—"Bromine of commerce, pure." *Br.*

Cadmium Iodide.—"Cadmium Iodide, CdI_2, of commerce, pure." *Br.*

Calcium Carbonate.—"Calcium Carbonate, the pure white marble, or calc spar, of commerce." *Br.*

Calcium Hydroxide.—"Calcium Hydroxide of the British Pharmacopœia." *Br.*

Calcium Oxide.—"Calcium Oxide, the Lime of the British Pharmacopœia." *Br.*

Calcium Sulphate.—"Calcium Sulphate, $CaSO_4,2H_2O$, native, pure." *Br.*

Carbon Disulphide.—"Carbon Disulphide of the British Pharmacopœia." *Br.*

Carbon Tetrachloride.—"Carbon Tetrachloride CCl_4, of commerce, pure." *Br.*

Chlorine.—"Chlorine, a gas prepared by the interaction of hydrochloric acid and manganese peroxide, and purified by passing through a small quantity of water contained in a wash bottle." *Br.*

Chloroform.—"Chloroform of the British Pharmacopœia." *Br.*

Chloroform Water.—"Chloroform Water of the British Pharmacopœia." *Br.*

Citric Acid.—"Citric Acid of the British Pharmacopœia." *Br.*

Collodion.—"Collodion of the British Pharmacopœia." *Br.*

Copper.—"Copper in foil, wire, or turnings." *Br.*

Copper Acetate.—"Copper Acetate, $Cu(C_2H_3O_2)_2,H_2O$, of commerce, crystalline, pure." *Br.*

Copper Carbonate.—"Copper Carbonate, precipitated, of commerce." *Br.*

Copper Sulphate.—"Copper Sulphate of the British Pharmacopœia." *Br.*

Ether.—"Ether of the British Pharmacopœia." *Br.*

Ferric Ammonium Sulphate.—"Ferric Ammonium Sulphate, $Fe_2(SO_4)_3,(NH_4)_2SO_4,24H_2O$, of commerce, pure." *Br.*

Ferric Chloride.—"Ferric Chloride of commerce, pure, anhydrous." *Br.*

Ferrous Sulphate.—"Ferrous Sulphate of the British Pharmacopœia." *Br.*

Fuchsin.—"Fuchsin of commerce, pure." *Br.*

Glycerin.—"Glycerin of the British Pharmacopœia." *Br.*

Hydrochloric Acid.—"Hydrochloric Acid of the British Pharmacopœia." *Br.*

Hydrochloric Acid, Diluted.—"Diluted Hydrochloric Acid of the British Pharmacopœia." *Br.*

Hydrochloric Acid, Gaseous.—"Gaseous Hydrochloric Acid, HCl, dry, prepared by the interaction of sulphuric acid and common salt." *Br.*

Hydrogen Sulphide.—Synonym—*Sulphuretted Hydrogen.* "A gas prepared by the action of hydrochloric acid on commercial ferrous sulphide. It will be sufficiently pure after passing through two wash-bottles containing water. A solution of the gas in water may also be employed, but only if it smells strongly of the gas, and yields an abundant black precipitate with solution of lead acetate." *Br.*

Hydroxylamine Hydrochloride.—"Hydroxylamine Hydrochloride, NH_2OH,HCl, of commerce, pure." *Br.*

Hypophosphorous Acid.—"Hypophosphorous Acid of commerce, specific gravity 1.137." *Br.*

Indigo.—"Indigo, a blue pigment prepared from various species of Indigofera, Linn." *Br.*

Iodic Acid.—"Iodic Acid, HIO_3, of commerce, pure." *Br.*

Iodine.—"Iodine of the British Pharmacopœia." *Br.*

Iron.—"Iron of the British Pharmacopœia." *Br.*

Isinglass.—"Isinglass, the swimming bladder or sound of various species of Acipenser, Linn., prepared, and cut into shreds." *Br.*

Lead Acetate.—"Lead Acetate of the British Pharmacopœia." *Br.*

Lead Nitrate.—"Lead Nitrate, $Pb(NO_3)_2$, of commerce, pure." *Br.*

Lead Oxide.—"Lead Oxide of the British Pharmacopœia." *Br.*

Lead Peroxide.—"Lead Peroxide, PbO_2, of commerce, pure." *Br.*

Lime.—"Lime of the British Pharmacopœia." *Br.*

Litmus.—"Litmus, a blue pigment prepared from various species of Roccella, DC. Litmus is used in several forms; for example, Solution of Litmus (Appendix II); Blue Litmus Paper, made by impregnating unglazed white paper with a solution of litmus; and Red Litmus Paper, made by impregnating the paper with the solution reddened by the previous addition of a very minute quantity of sulphuric acid. Litmus may also be employed in the solid form." *Br.*

Magnesia, Heavy.—"Heavy Magnesia of the British Pharmacopœia." *Br.*

Manganese Peroxide.—"Manganese Peroxide, MnO_2, the powdered native pyrolusite." *Br.*

Mercurous Chloride.—"Mercurous Chloride of the British Pharmacopœia." *Br.*

Methyl Orange.—"Methyl Orange, pure sodium dimethyl-amido-azo-benzene-sulphonate, $NaC_{14}H_{14}N_3SO_3$, of commerce." *Br.*

Milk of Lime.—"Lime, 100 grammes; Distilled Water, 200 millilitres; mix." *Br.*

Morphinated Water.—"Morphinated Water, prepared by digesting pure Morphine in Chloroform Water for seven days at a temperature of 15.5° C. (59.9° F.), shaking occasionally so as to obtain a saturated solution of the alkaloid, and filtering from the undissolved morphine." *Br.*

Morphine.—"Morphine, the precipitate obtained on adding solution of ammonia, in slight excess, to the solution of a pure morphine salt in *water*, the precipitate being washed with water until free from ammonium, salt." *Br.*

Mucilage of Gum Acacia.—"Mucilage of Gum Acacia of the British Pharmacopœia." *Br.*

Mucilage of Starch.—"Triturate 1 gramme of Starch with a small quantity of Distilled Water to form a smooth paste; add more Distilled Water, gradually, to produce 50 millilitres of mixture; boil for a few minutes, constantly stirring; cool." *Br.* Mucilage of starch must be recently prepared.

Nitric Acid.—"Nitric Acid of the British Pharmacopœia." *Br.*

Nitric Acid, Diluted.—"Diluted Nitric Acid of the British Pharmacopœia." *Br.*

Nitric Acid, Fuming.—"Fuming Nitric Acid of commerce, specific gravity 1.5." *Br.*

Oil of Turpentine.—"Oil of Turpentine of the British Pharmacopœia." *Br.*

Olive Oil.—"Olive Oil of the British Pharmacopœia." *Br.*

Oxalic Acid.—"Oxalic Acid, $H_2C_2O_4,2H_2O$, of commerce, pure." *Br.*

Paraffin, Soft.—"Soft Paraffin of the British Pharmacopœia." *Br.*

Petroleum Spirit.—Synonym—*Petroleum Ether.* "A colourless, very volatile and highly inflammable liquid obtained from petroleum, and consisting of a mixture of the lower members of the paraffin series of hydrocarbons. Boiling point 50° to 60° C. (122°-140° F.). Specific gravity 0.670 to 0.700." *Br.*

Phenol.—"Phenol of the British Pharmacopœia." *Br.*

Phenol-Disulphonic Acid.—"Heat 3 grammes of Phenol with 20 millilitres of Sulphuric Acid on a water-bath for six hours. Transfer the resulting liquid to a stoppered bottle." *Br.*

Phenolphthalein.—"Phenolphthalein of the British Pharmacopœia." *Br.*

Phosphoric Acid, Concentrated.—"Concentrated Phosphoric Acid of the British Pharmacopœia." *Br.*

Phosphoric Acid, Syrupy.—"Syrupy Phosphoric Acid of commerce, specific gravity 1.750." *Br.*

Picric Acid.—"Picric Acid of the British Pharmacopœia." *Br.*

Platinic Chloride.—"Platinic Chloride of commerce, pure." *Br.*

Potassium Bichromate.—"Potassium Bichromate of the British Pharmacopœia." *Br.*

Potassium Chlorate.—"Potassium Chlorate of the British Pharmacopœia." *Br.*

Potassium Chromate.—"Potassium Chromate, K_2CrO_4, of commerce, pure." *Br.*

Potassium Cyanide.—"Potassium Cyanide of commerce. Contains not less than 90 per cent. of pure potassium cyanide, KCN." *Br.*

Potassium Ferricyanide.—"Potassium Ferricyanide, $K_6Fe_2C_{12}N_{12}$, of commerce, pure." *Br.*

Potassium Ferrocyanide.—"Potassium Ferrocyanide, $K_4FeC_6N_6,3H_2O$, of commerce, pure." *Br.*

Potassium Hydrogen Sulphite.—Synonym—*Acid Potassium Sulphite.* "$KHSO_3$, of commerce, pure." *Br.*

Potassium Hydroxide.—"Potassium Hydroxide of the British Pharmacopœia." *Br.*

Potassium Iodide.—"Potassium Iodide of the British Pharmacopœia." *Br.*

Potassium Nitrate.—"Potassium Nitrate of the British Pharmacopœia." *Br.*

Potassium Permanganate.—"Potassium Permanganate of the British Pharmacopœia." *Br.*

Potassium Sulphate.—"Potassium Sulphate of the British Pharmacopœia." *Br.*

Resorcin.—"Resorcin of the British Pharmacopœia." *Br.*

Salicylic Acid.—"Salicylic Acid of the British Pharmacopœia." *Br.*

Sodium Acetate.—"Sodium Acetate, $NaC_2H_3O_2,3H_2O$, of commerce, pure." *Br.*

Sodium Acetate, Anhydrous.—"Anhydrous Sodium Acetate, $NaC_2H_3O_2$, of commerce, pure." *Br.*

Sodium Arsenate, Anhydrous.—"Anhydrous Sodium Arsenate of the British Pharmacopœia." *Br.*

Sodium Bicarbonate.—"Sodium Bicarbonate of the British Pharmacopœia." *Br.*

Sodium Carbonate.—"Sodium Carbonate of the British Pharmacopœia." *Br.*

Sodium Carbonate, Exsiccated.—"Exsiccated Sodium Carbonate of the British Pharmacopœia." *Br.*

Sodium Chloride.—"Sodium Chloride of the British Pharmacopœia." *Br.*

Sodium Hydrogen Sulphite.—Synonym—*Acid Sodium Sulphite,* "$NaHSO_3$, of commerce, pure." *Br.*

Sodium Hydroxide.—"Sodium Hydroxide of commerce, purified by means of alcohol." *Br.*

Sodium Nitrite.—"Sodium Nitrite of the British Pharmacopœia." *Br.*

Sodium Potassium Tartrate.—"Sodium Potassium Tartrate of the British Pharmacopœia." *Br.*

Sodium Sulphate.—"Sodium Sulphate of the British Pharmacopœia." *Br.*

Sodium Sulphate, Anhydrous.—"The Sodium Sulphate of the British Pharmacopœia, rendered anhydrous by heat." *Br.*

Sodium Sulphide.—"Sodium Sulphide, $Na_2S,9H_2O$, of commerce, pure." *Br.*

Sodium Sulphite.—"Sodium Sulphite of the British Pharmacopœia." *Br.*

Sodium Thiosulphate.—"Sodium Thiosulphate, $Na_2S_2O_3,5H_2O$, of commerce, pure." *Br.*

Sugar, Refined.—"Refined Sugar of the British Pharmacopœia." *Br.*

Sulphur, Precipitated.—"Precipitated Sulphur of the British Pharmacopœia." *Br.*

Sulphuric Acid.—"Sulphuric Acid of the British Pharmacopœia." *Br.*

Sulphuric Acid, Diluted.—"Diluted Sulphuric Acid of the British Pharmacopœia." *Br.*

Talc, Powdered.—"A natural magnesium silicate, powdered and purified by boiling with dilute hydrochloric acid, washing with distilled water until neutral to litmus, and drying." *Br.*

Tartaric Acid.—"Tartaric Acid of the British Pharmacopœia." *Br.*

Tin.—"Tin, granulated by letting drops of the metal in the molten state fall into water. Yields no characteristic reactions for lead, copper, iron, or zinc." *Br.*

Turmeric.—"The dried rhizome of Curcuma longa, *Linn.* It is usually employed in the form of a tincture prepared, by the process of maceration, from the bruised rhizome, in the proportion of 1 gramme to 6 millilitres of Alcohol (90 per cent.), or in the form of paper prepared by steeping unglazed white paper in the tincture and drying." *Br.*

Water.—"The Distilled Water of the British Pharmacopœia." *Br.*

Zinc.—"The laminated or granulated metal. Completely dissolved by diluted hydrochloric acid, the solution yielding no characteristic reactions for lead, copper, cadmium, arsenic, tin or iron." *Br.*

Zinc Carbonate.—"Zinc Carbonate of the British Pharmacopœia." *Br.*

APPENDIX II. *Br.*

Solutions Employed in Chemical Testing. *Br.*

Solution of Albumen.—" Albumen, 20 millilitres; Distilled Water, 80 millilitres. Mix by trituration in a mortar, and filter through clean tow previously moistened with Distilled Water. Solution of Albumen must be recently prepared. The strength of the Solution may be adjusted to suit particular requirements." *Br.*

Solution of Ammonia.—"Solution of Ammonia of the British Pharmacopœia." *Br.*

Solution of Ammonia, Strong.—"Strong Solution of Ammonia of the British Pharmacopœia." *Br.*

Solution of Ammonium Acetate.—"Solution of Ammonium Acetate of the British Pharmacopœia." *Br.*

Solution of Ammonium Carbonate.—"Ammonium Carbonate, 5.0 grammes; Solution of Ammonia, 7.5 millilitres; Distilled Water, sufficient to produce 100.0 millilitres; Dissolve; filter if necessary." *Br.*

Solution of Ammonium Chloride.—" Ammonium Chloride, 10 grammes; Distilled Water sufficient to produce 100 millilitres. Dissolve; filter if necessary." *Br.*

Solution of Ammonium Chloride (Nessler's).—" Ammonium Chloride, 3.15 grammes; Distilled Water, free from ammonia, sufficient to produce 1000.00 millilitres. Dissolve." *Br.*

Solution of Ammonium Chloride, Dilute (Nessler's).—" Solution of Ammonium Chloride (Nessler's), 10 millilitres; Distilled Water, free from ammonia, sufficient to produce 1000 millilitres. Mix." *Br.*

Solution of Ammonium Citrate.—"Solution of Ammonium Citrate of the British Pharmacopœia." *Br.*

Solution of Ammonium Hydrosulphide.—" Saturate one hundred and twenty millilitres of Solution of Ammonia with washed Hydrogen Sulphide; add eighty millilitres of Solution of Ammonia. This Solution must be recently prepared." *Br.*

Solution of Ammonium Molybdate.—" Ammonium Molybdate, 10 grammes; Distilled Water, sufficient to produce 100 millilitres. Dissolve; filter if necessary." *Br.*

Solution of Ammonium Oxalate.—" Ammonium Oxalate, 2.5 grammes; Distilled Water sufficient to produce 100.0 millilitres. Dissolve; filter if necessary." *Br.*

Solution of Auric Chloride.—" Auric Chloride, 2 grammes; Distilled Water, sufficient to produce 100 millilitres. Dissolve; filter if necessary." *Br.*

Solution of Barium Chloride.—" Barium Chloride, in crystals, 10 grammes; Distilled Water sufficient to produce 100 millilitres. Dissolve; filter if necessary." *Br.*

Solution of Barium Hydroxide.—" Barium Hydroxide, 3 grammes; Distilled Water, recently boiled, sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Boric Acid.—"Boric Acid, 2.5 grammes; Alcohol (90 per cent.) sufficient to produce 100.0 millilitres; dissolve; filter if necessary." *Br.*

Solution of Bromine.—" A saturated solution of Bromine in Distilled Water." *Br.*

Solution of Cadmium Iodide.—" Cadmium Iodide, 5 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Calcium Chloride.—" Calcium Chloride, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Calcium Sulphate.—" A saturated solution of Calcium Sulphate in Distilled Water." *Br.*

Solution of Chlorinated Soda.—"Solution of Chlorinated Soda of the British Pharmacopœia." *Br.*

Solution of Chlorine.—" A saturated solution of Chlorine in Distilled Water. This Solution must be recently prepared." *Br.*

Solution of Chromic Acid.—"Solution of Chromic Acid of the British Pharmacopœia." *Br.*

Solution of Copper Acetate.—" Copper Acetate, 5 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Copper Acetate, Diluted.—" Solution of Copper Acetate, 1 millilitre; Distilled Water sufficient to produce 100 millilitres. Mix." *Br.*

Solution of Copper Ammonio-Sulphate.—" Copper Sulphate, in crystals, 5 grammes; Solution of Ammonia, a sufficient quantity; Distilled Water sufficient to produce 100 millilitres. Dissolve the Copper Sulphate in one hundred and sixty millilitres of the Distilled Water, and cautiously add the Solution of Ammonia to the liquid until the precipitate first formed is nearly dissolved; filter the product; finally add to the filtrate sufficient of the Distilled Water to produce the required volume." *Br.*

Solution of Copper Oxide, Ammoniacal.—" Copper Carbonate, 5 grammes; Strong Solution of Ammonia, 100 millilitres. Shake together occasionally during twelve hours; set aside for twenty-four hours, and pour off the clear liquid. This Solution must be recently prepared." *Br.*

Solution of Copper Sulphate.—" Copper Sulphate, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Ferric Sulphate.—"Solution of Ferric Sulphate of the British Pharmacopœia." *Br.*

Solution of Ferrous Sulphate.—" Ferrous Sulphate, 2 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary. This Solution must be recently prepared." *Br.*

Solution of Formaldehyde.—"Solution of Formaldehyde of the British Pharmacopœia." *Br.*

Solution of Fuchsin, Decolorized.—" Dissolve one gramme of Fuchsin in five hundred millilitres of hot Distilled Water; add slowly twenty millilitres of a saturated aqueous solution of Acid Sodium Sulphite and then, also slowly, ten millilitres of Hydrochloric Acid, the mixture being kept well shaken. Cool and add sufficient Distilled Water to produce one thousand millilitres." *Br.*

Solution of Hydrogen Peroxide.—"Solution of Hydrogen Peroxide of the British Pharmacopœia." *Br.*

Solution of Indigo Sulphate.—" Indigo, dry and in fine powder, 0.1 gramme; Sulphuric Acid 100.0 millilitres. Mix the Indigo with one millilitre of the Sulphuric Acid in a small test-tube, and heat in boiling water for an hour; pour the product into the remainder of the Sulphuric Acid; shake the mixture; decant the clear liquid." *Br.*

Solution of Isinglass.—" Isinglass, 2 grammes; Distilled Water, sufficient to produce 100 millilitres. Mix, and digest for half an hour on a water-bath with repeated shaking; filter through clean tow previously moistened with Distilled Water. This Solution must be recently prepared." *Br.*

Solution of Lead Acetate.—" Lead Acetate, 10 grammes; Distilled Water, recently boiled, sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Lead Subacetate.—"The Strong Solution of Lead Subacetate of the British Pharmacopœia, diluted, if necessary, with Distilled Water." *Br.*

Solution of Lime.—Synonym—*Solution of Calcium Hydroxide.* "Solution of Lime of the British Pharmacopœia." *Br.*

Solution of Litmus.—" Litmus, in powder, 10 grammes; Alcohol (90 per cent.), 100 millilitres; Distilled Water, 100 millilitres. Boil the Litmus with forty millilitres of the Alcohol for one hour; pour away the clear liquid; repeat this operation with thirty millilitres of the Alcohol, and a third time with the remainder of the Alcohol. Digest the washed Litmus in the Distilled Water, and filter." *Br.*

Solution of Magnesium Ammonio-Sulphate.—" Magnesium Sulphate, 10 grammes; Ammonium Chloride, 20 grammes; Solution of Ammonia, 42 millilitres; Distilled Water, 80 millilitres. Dissolve the Magnesium Sulphate and Ammonium Chloride in the Distilled Water; add the Solution of Ammonia, and set the mixture aside for a few days in a well-closed bottle; decant and filter." *Br.*

Solution of Magnesium Sulphate.—" Magnesium Sulphate, 10 grammes; Distilled Water sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Mercurous Nitrate.—"Mercury, 2 grammes; Nitric Acid, 1 millilitre; Distilled Water, a sufficient quantity. To the Mercury, in a small dish, add one millilitre of Distilled Water and the Nitric Acid, and set the whole aside for twenty-four hours in a cool dark place; drain the resulting crystals; dissolve them in two hundred millilitres of Distilled Water." *Br.*

Solution of Mercury Nitrate.—Synonym—*Millon's Reagent.* "Mercury, 3 millilitres; Fuming Nitric Acid, 27 millilitres; Distilled Water, a sufficient quantity. Dissolve the Mercury in the Fuming Nitric Acid without heat; dilute the solution with an equal volume of Distilled Water. This Solution must be recently prepared." *Br.*

Solution of Methyl Orange.—" Methyl Orange, 0.2 gramme; Alcohol (90 per cent.), 25.0 millilitres; Distilled Water, sufficient to produce 100.0 millilitres; dissolve." *Br.*

Solution of Phenolphthalein.—" Phenolphthalein, 0.2 gramme; Alcohol (90 per cent.), 60.0 millilitres; Distilled Water, sufficient to produce 100.0 millilitres; dissolve." *Br.*

Solution of Picric Acid.—" Picric Acid, 0.66 gramme; Distilled Water, sufficient to produce 100.00 millilitres; dissolve." *Br.*

Solution of Platinic Chloride.—" Platinic Chloride, 5 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve." *Br.*

Solution of Potassio-Cupric Tartrate.—Synonym—*Fehling's Solution.* *Br.*

" No. 1. Copper Sulphate, in crystals, 34.64 grammes; Sulphuric Acid, 0.50 millilitre; Distilled Water, sufficient to produce 500.00 millilitres; dissolve.

"No. 2. Sodium Potassium Tartrate, 176 grammes; Sodium Hydroxide, 77 grammes; Distilled Water sufficient to produce 500 millilitres; dissolve. Mix equal volumes of the solutions No. 1 and No. 2 at the time of using." *Br.*

Solution of Potassio-Mercuric Iodide.—Synonym—*Mayer's Reagent.* "Mercuric Chloride, 1.355 grammes; Potassium Iodide, 5.000 grammes; Distilled Water, sufficient to produce 100.000 millilitres. Dissolve the Mercuric Chloride in sixty millilitres of the Distilled Water; dissolve the Potassium Iodide in twenty millilitres of the Distilled Water; mix the two solutions, and add sufficient Distilled Water to produce the required volume." *Br.*

Solution of Potassio-Mercuric Iodide, Alkaline.—Synonym—*Nessler's Reagent.* "Potassium Iodide, 3.5 grammes; Mercuric Chloride, sufficient quantity; Sodium Hydroxide, 12.0 grammes; Distilled Water, sufficient to produce 100.0 millilitres. Dissolve the Potassium Iodide and one and a quarter grammes of Mercuric Chloride in eighty millilitres of Distilled Water; to this liquid add a cold saturated aqueous solution of Mercuric Chloride, with constant stirring, until a slight red precipitate remains; add the Sodium Hydroxide and dissolve; then add a little more of the aqueous solution of Mercuric Chloride, and sufficient Distilled Water to produce the required volume." *Br.*

Solution of Potassium Acetate.—" Potassium Acetate, 10 grammes; Distilled Water sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Acid Potassium Tartrate.—" A saturated solution of Acid Potassium Tartrate in Distilled Water." *Br.*

Solution of Potassium Carbonate.—" Potassium Carbonate, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Potassium Chromate.—" Potassium Chromate, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Potassium Cyanide.—" Potassium Cyanide, 10 grammes; Distilled Water, 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Potassium Ferricyanide.—" Potassium Ferricyanide, in crystals, 5 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary. This Solution must be recently prepared." *Br.*

Solution of Potassium Ferrocyanide.—" Potassium Ferrocyanide, in crystals, 5 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Potassium Hydroxide.—"Solution of Potash of the British Pharmacopœia." *Br.*

Solution of Potassium Hydroxide, Alcoholic.—" Potassium Hydroxide, 10 grammes; Alcohol (90 per cent.), sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Potassium Iodide.—" Potassium Iodide, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Potassium Permanganate.—"Solution of Potassium Permanganate of the British Pharmacopœia." *Br.*

Solution of Pyroxylin.—"Solution of Pyroxylin, the Collodion of the British Pharmacopœia." *Br.*

Solution of Silver Ammonio-Nitrate.—" Silver Nitrate, in crystals, 2.5 grammes; Solution of Ammonia, 10.0 millilitres, or a sufficient quantity; Distilled Water, sufficient to produce 100.0 millilitres. Dissolve the Silver Nitrate in eighty millilitres of the Distilled Water, and cautiously add the Solution of Ammonia to the liquid until the precipitate first formed is nearly dissolved; set aside; decant; finally add sufficient Distilled Water to produce the required volume." *Br.*

Solution of Silver Nitrate.—" Silver Nitrate, 5 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve." *Br.*

Solution of Sodium Acetate.—" Sodium Acetate, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Sodium Carbonate.—" Sodium Carbonate, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Sodium Hydroxide.—" Sodium Hydroxide, 20 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Sodium Phosphate.—" Sodium Phosphate, in crystals, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Sodium Sulphate.—" Sodium Sulphate, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Sodium Sulphide.—"Sodium Sulphide, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Stannous Chloride.—"Tin, granulated, 20 grammes; Hydrochloric Acid, 60 millilitres; Distilled Water, sufficient to produce 100 millilitres. Dilute the Hydrochloric Acid with twenty millilitres of the Distilled Water, and, having added the Tin, apply heat gently until gas ceases to be evolved; add sufficient Distilled Water to produce the required volume, allowing the undissolved Tin to remain in the Solution." *Br.*

Solution of Sulphurous Acid.—"The Sulphurous Acid of the British Pharmacopœia." *Br.*

Solution of Tannic Acid.—"Tannic Acid, 10 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve. This Solution must be recently prepared." *Br.*

Solution of Tartarated Antimony.—"Tartarated Antimony, 5 grammes; Distilled Water, boiling, sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Solution of Tartaric Acid.—"Tartaric Acid, in crystals, 12.5 grammes; Alcohol (90 per cent.), 25.0 millilitres; Distilled Water, sufficient to produce 100.0 millilitres. Dissolve the Tartaric Acid in sixty millilitres of the Distilled Water; add the Alcohol; add sufficient Distilled Water to produce the required volume." *Br.*

Test-Solution of Ferric Chloride (T. Sol.).—"Ferric Chloride, 5 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary." *Br.*

Test-Solution of Mercuric Chloride (T. Sol.).—"Mercuric Chloride, 5 grammes; Distilled Water, sufficient to produce 100 millilitres; dissolve; filter if necessary." Br.

APPENDIX III. Br.

Solutions Employed in Volumetric Determinations.

Solution of Ammonium Thiocyanate, N/10.—"Ammonium Thiocyanate dissolved in Distilled Water to contain in 1000 millilitres 7.612 grammes of ammonium thiocyanate, NH_4SCN." *Br.*

Solution of Hydrochloric Acid, N/1, N/10.—"Hydrochloric Acid diluted with Distilled Water to contain in 1000 millilitres the following quantities of hydrochloric acid, HCl: for N/1, 36.468 grammes HCl; for N/10, 3.646 grammes HCl." *Br.*

Solution of Hydroxylamine Hydrochloride, N/2.—"Hydroxylamine Hydrochloride dissolved in a mixture of equal volumes of Alcohol (90 per cent.) and Alcohol (70 per cent.) to contain in 1000 millilitres 34.751 grammes of hydroxylamine hydrochloride, NH_2OH,HCl." *Br.*

Solution of Iodine, N/10.—"Iodine and Potassium Iodide dissolved in Distilled Water to contain in 1000 millilitres 12.692 grammes of iodine, I, and 18 grammes of Potassium Iodide." *Br.*

Solution of Oxalic Acid, N/1, N/10.—"Oxalic Acid dissolved in Distilled Water to contain in 1000 millilitres the following quantities of oxalic acid, $H_2C_2O_4,2H_2O$: for N/1, 63.024 grammes $H_2C_2O_4,2H_2O$; for N/10, 6.302 grammes $H_2C_2O_4,2H_2O$." *Br.*

Solution of Potassium Bichromate, N/1, N/10.—"Potassium Bichromate dissolved in Distilled Water to contain in 1000 millilitres the following quantities of potassium bichromate, $K_2Cr_2O_7$: for N/1, 49.033 grammes $K_2Cr_2O_7$; for N/10, 4.903 grammes $K_2Cr_2O_7$." *Br.*

Solution of Potassium Hydroxide, Alcoholic, N/1, N/2, N/10.—"Potassium Hydroxide dissolved in Alcohol (90 per cent.) to contain in 1000 millilitres the following quantities of potassium hydroxide, KOH: for N/1, 56.108 grammes KOH; for N/2, 28.054 grammes KOH; for N/10, 5.610 grammes KOH. These Solutions are colourless, or not more than faintly yellow." *Br.*

Solution of Potassium Permanganate, N/10.—"Potassium Permanganate dissolved in Distilled Water to contain in 1000 millilitres 3.161 grammes of potassium permanganate, $KMnO_4$." *Br*

Solution of Silver Nitrate, N/10.—"Silver Nitrate dissolved in Distilled Water to contain in 1000 millilitres 16.989 grammes of silver nitrate, $AgNO_3$." *Br.*

Solution of Sodium Hydroxide, N/1, N/2, N/5, N/10, N/20.—"Sodium Hydroxide dissolved in Distilled Water to contain in 1000 millilitres the following quantities of sodium hydroxide, NaOH: for N/1, 40.008 grammes NaOH; for N/2, 20.004 grammes NaOH; for N/5, 8.001 grammes NaOH; for N/10, 4.000 grammes NaOH; for N/20, 2.000 grammes NaOH." *Br.*

Solution of Sodium Thiosulphate, N/10.—"Sodium Thiosulphate dissolved in Distilled Water to contain in 1000 millilitres 24.822 grammes of sodium thiosulphate, $Na_2S_2O_3,5H_2O$." *Br.*

Solution of Sulphuric Acid, N/1, N/2, N/10, N/20, N/100.—"Sulphuric Acid diluted with Distilled Water to contain in 1000 millilitres the following quantities of sulphuric acid, H_2SO_4: for N/1, 49.043 grammes H_2SO_4; for N/2, 24.521 grammes H_2SO_4; for N/10, 4.904 grammes H_2SO_4; for N/20, 2.452 grammes H_2SO_4; for N/100, 0.490 gramme H_2SO_4." *Br.*

Indicators of the Termination of Reactions in Volumetric Determinations. Br.

Mucilage of Starch.—"It gives an intensely blue colour with iodine, at ordinary temperatures." *Br.*

Solution of Ferric Sulphate.—"Solution of Ferric Sulphate, of the British Pharmacopœia, gives a deep red colour with ammonium thiocyanate." *Br.*

Solution of Litmus.—"It gives a red colour with acids and a blue colour with alkalies. Carbon dioxide, if present in the solution, must be previously expelled by boiling." *Br.*

Solution of Methyl Orange.—"It gives a pink colour with mineral acids and a yellow colour with alkalies." *Br.*

Solution of Phenolphthalein.—"It gives with alkalies a red colour, which is discharged by acids." *Br.*

Solution of Potassium Ferricyanide.—"It gives an intensely blue precipitate or coloration with ferrous salts, but none with ferric salts." *Br.*

Tincture of Cochineal.—"Tincture of Cochineal, of the British Pharmacopœia, gives a purple colour with alkalies and a brownish-yellow colour with acids." *Br.*

APPENDIX IV. Br.

Reactions and Tests for Substances Mentioned in the Text of the British Pharmacopœia

Acetates.—"Neutral acetates are decomposed by heat, yielding vapours which possess a characteristic acetous odour. Hydrogen acetate and ethyl acetate have characteristic odours. Acetates when warmed with *sulphuric acid* yield vapours of hydrogen acetate; or, when warmed with *sulphuric acid* and a small quantity of *alcohol* (90 per cent.), yield ethyl acetate. *T. Sol. of ferric chloride* produces a deep-red coloration with neutral or faintly acid acetates, and the resulting liquid on boiling yields a reddish-brown precipitate. On adding *hydrochloric acid* the red solution turns yellow." *Br.*

Aluminium.—"*Solution of ammonia* or *solution of ammonium hydrosulphide* produces a white gelatinous precipitate, soluble in *hydrochloric acid*, in *acetic acid*, and in *solution of sodium hydroxide*, but nearly insoluble in *solution of ammonia* and in solutions of ammonium salts, and quite insoluble when the solutions are boiled." *Br.*

Ammonium Salts.—"Ammonium salts volatilise when strongly heated, generally without residue. When heated with *solution of sodium hydroxide*, ammonia is evolved, recognisable by its odour. *Solution of platinic chloride* produces with ammonium salts acidified with *hydrochloric acid* a yellow crystalline precipitate, especially in the presence of alcohol. On ignition, this precipitate leaves a residue of platinum only." *Br.*

Antimony.—"*Hydrogen sulphide* produces, in slightly acid solutions, an orange-coloured precipitate, soluble in *solution of sodium hydroxide*, and *of ammonium hydrosulphide*, and in warm *hydrochloric acid* with evolution of hydrogen sulphide, but almost insoluble in solution of Ammonium Carbonate. Nascent hydrogen, generated by the interaction of *zinc* and *diluted sulphuric acid*, partially converts antimony compounds into hydrogen antimonide. A cold porcelain tile held in the flame of this gas acquires a dark metallic deposit which is not appreciably dissolved by *solution of chlorinated soda*. Nascent hydrogen, generated by the interaction of *zinc* and *solution of sodium hydroxide*, does not convert antimony into hydrogen antimonide. If one end of a strip or rod of *zinc* be allowed to rest on a platinum capsule containing an acidified solution of an antimony compound, the other end being in the solution, the antimony is precipitated on the platinum as a black, adherent, non-granular stain, insoluble in *hydrochloric acid*. Bright *copper* foil precipitates antimony from solutions, and the antimony may be volatilised by heat in an open tube, condensing as a white amorphous sublimate of oxides of antimony near to the copper." *Br.*

Arsenic.—"*Hydrogen sulphide* produces in solutions containing *hydrochloric acid* a yellow precipitate, soluble in *solution of sodium hydroxide*, and *of ammonium hydrosulphide*, and in solution of Ammonium Carbonate, but reprecipitated on addition of *hydrochloric acid*. The precipitate is insoluble in *hydrochloric acid*. Nascent hydrogen, generated by the interaction of *zinc* and *diluted sulphuric acid*, converts arsenic compounds into hydrogen arsenide. A cold porcelain tile held in the flame of this gas acquires a dark metallic deposit, which is readily dissolved by *solution of chlorinated soda*. Nascent hydrogen, generated by the interaction of *zinc* and *solution of sodium hydroxide*, converts arsenic compounds into hydrogen arsenide. This gas gives a black stain to filter-paper soaked with *solution of silver nitrate* and placed as a cap over the tube in which the test is being performed. Bright *copper* foil precipitates arsenic from solutions acidified by *hydrochloric acid*, and the arsenic may be volatilised by heat in an open tube, and condensers, at some distance from the copper, as a white sublimate of characteristic octahedral crystals of arsenious oxide.

ARSENITES.—Solutions of arsenites yield a yellow precipitate with *solution of silver ammonio-nitrate*.

ARSENATES.—Solutions of arsenates yield a reddish-chocolate precipitate with *solution of silver ammonio-nitrate*. *Solution of magnesium ammonio-sulphate* produces a white crystalline precipitate." *Br.*

Bicarbonates. *See* "**Carbonates.**"

Bismuth.—"*Hydrogen sulphide* produces a brownish-black precipitate, insoluble in *solution of sodium hydroxide*, in *diluted hydrochloric acid*, and in *solution of ammonium hydrosulphide*, but soluble in warm *nitric acid*. *Solution of sodium hydroxide*, or of *ammonia*, except in the presence of citrates, produces a white precipitate insoluble in excess of the precipitant. Dilute solution of *sodium chloride* in large excess produces in solutions which are not too acid a white precipitate, insoluble in *solution of tartaric acid*." *Br.*

Bromates.—"From bromates *solution of sulphurous acid* liberates bromine, recognisable by its odour and appearance. After ignition with charcoal bromates are converted into bromides, and the latter yield their characteristic reactions." *Br.*

Bromides.—"*Solution of silver nitrate* produces a yellowish curdy precipitate, somewhat soluble in strong but almost insoluble in diluted *solution of ammonia*, and insoluble in *nitric acid*. *Solution of chlorine* liberates bromine, soluble in two or three drops of *carbon disulphide* or of *chloroform*, and forming a reddish solution. Bromine is liberated when a bromide is heated with *sulphuric acid* and *manganese peroxide*, or *potassium bichromate*, the vapour giving an orange-yellow colour to filter-paper soaked in *mucilage of starch*. In testing for bromides in the presence of iodides, all iodine should first be removed by boiling the aqueous solution with excess of *lead peroxide*." *Br.*

Cadmium.—"*Hydrogen sulphide* produces a yellow precipitate, insoluble in cold *diluted hydrochloric acid*, in *solution of ammonium hydrosulphide*, and in *solution of sodium hydroxide*, but soluble in *nitric acid*, in hot *diluted hydrochloric acid*, and in hot *diluted sulphuric acid*. *Solution of sodium hydroxide* produces a white precipitate insoluble in excess. *Solution of ammonia* produces a white precipitate readily soluble in excess." *Br.*

Calcium.—"*Solution of ammonium carbonate* produces a white precipitate which, after well boiling and allowing to cool, is insoluble in *solution of ammonium chloride*. *Solution of ammonium oxalate* produces a white precipitate, soluble in *hydrochloric acid* but insoluble in *acetic acid*. *Solution of potassium chromate* produces no precipitate." *Br.*

Carbonates and Bicarbonates.—"Dilute acids liberate carbon dioxide; the escaping gas is odourless, and produces a white precipitate in *solution of lime*. Soluble carbonates produce a brownish-red precipitate with *T. Sol. of mercuric chloride*, bicarbonates a whitish precipitate; the former produce a white precipitate with cold *solution of magnesium sulphate*, the latter do not." *Br.*

Chlorides.—"*Solution of silver nitrate* produces a white curdy precipitate, soluble in *solution of*

ammonia, but insoluble in *nitric acid*. A solid chloride or hydrochloride, when subjected to distillation with *sulphuric acid* and *potassium bichromate*, yields a reddish-brown distillate, which is decomposed by *water*. The resulting solution when nearly neutralised produces a yellow precipitate with *solution of lead acetate*. Heated with *manganese peroxide* and *sulphuric acid*, chlorides yield chlorine, recognisable by its odour and by giving a blue colour with *solution of potassium iodide* and *mucilage of starch*." *Br.*

Citrates.—" Citrates become charred when heated. *Solution of calcium chloride* added in excess produces, when boiled with a neutral solution of a citrate, a white precipitate. *Solution of silver nitrate* produces in solutions of neutral citrates a white precipitate soluble in *solution of ammonia*. A mirror is not formed on the sides of the tube when the ammoniacal solution is warmed." *Br.*

Copper.—" *Hydrogen sulphide* produces a brownish-black precipitate, insoluble in *diluted hydrochloric acid* and in *solution of sodium hydroxide*, almost insoluble in *solution of ammonium hydrosulphide*, but decomposed and dissolved by boiling *nitric acid*. *Solution of sodium hydroxide* produces a bulky light-blue precipitate which becomes brownish-black on boiling. *Solution of ammonia* added in small quantity to a neutral solution of a copper salt produces a greenish-blue precipitate which readily dissolves in excess of the precipitant, forming a deep-blue solution. *Solution of potassium ferrocyanide* produces a reddish-brown precipitate, or in very dilute solutions a reddish-brown coloration." *Br.*

Cyanides.—" *Solution of silver nitrate* produces a white curdy precipitate, soluble in *solution of potassium cyanide*, in *solution of ammonia*, and in boiling *nitric acid*. When to a soluble cyanide there are added a few drops of a mixed solution of ferrous and ferric salts, then of *solution of sodium hydroxide*, and lastly excess of *hydrochloric acid*, a blue precipitate is produced. Mercury cyanide and silver cyanide decompose when heated, evolving (highly poisonous) cyanogen, which burns with a pink flame." *Br.*

Iodates.—" *Solution of silver nitrate* produces a white precipitate, sparingly soluble in *water* and in *diluted nitric acid*, but readily dissolved by *solution of ammonia*. *Solution of sulphurous acid* when added to the ammoniacal solution produces a pale yellow precipitate. A mixed *solution of potassium iodide* and *tartaric acid* added to a solution of an iodate liberates iodine, which produces a blue colour with *mucilage of starch*. *Solution of barium chloride* produces a white precipitate nearly insoluble in *water* and soluble with difficulty in *diluted nitric acid*. On the addition of *mucilage of starch* and *solution of sulphurous acid* a blue colour is produced." *Br.*

Iodides.—" *Solution of silver nitrate* produces a curdy yellow precipitate, insoluble in *nitric acid* and almost insoluble in *solution of ammonia*. *T. Sol. of mercuric chloride* produces a scarlet precipitate, slightly soluble in excess of this reagent, and very soluble in *solution of potassium iodide*. A small quantity of *solution of chlorine* added to a solution of an iodide liberates iodine, which colours *carbon disulphide* violet and *mucilage of starch* deep blue. Heated with *sulphuric acid* and *manganese peroxide* or *potassium bichromate* violet vapours of iodine are evolved." *Br.*

Iron.—"Reaction common to Ferrous and Ferric salts: *Solution of ammonium hydrosulphide* produces, in neutral solutions, a black precipitate soluble in cold *diluted hydrochloric acid* with evolution of hydrogen sulphide. Reactions characteristic of Ferrous salts: *Solution of potassium ferrocyanide* produces a white precipitate, rapidly turning blue, insoluble in *diluted hydrochloric acid*. *Solution of potassium ferricyanide* produces a dark-blue precipitate, insoluble in *diluted hydrochloric acid;* decomposed by *solution of sodium hydroxide*. *Solution of sodium hydroxide* produces a dull-green precipitate. Reactions characteristic of Ferric salts: *Solution of ammonium thiocyanate* produces a blood-red coloration which is discharged on the addition of *T. Sol. of mercuric chloride*. *Solution of potassium ferricyanide* produces a reddish-brown coloration but no precipitate. *Solution of potassium ferrocyanide* produces a dark-blue precipitate, insoluble in *diluted hydrochloric acid*. *Solution of sodium hydroxide* produces a reddish-brown precipitate, soluble in solution of *citric acid* or *tartaric acid*, and not formed in the presence of citrates or tartrates." *Br.*

Lead.—" *Hydrochloric acid* produces, except in very weak solutions, a white precipitate, soluble in boiling *water*, but re-deposited in crystals on cooling. *Hydrogen sulphide*, in not very strongly acid solutions, produces a black precipitate insoluble in *diluted hydrochloric acid*, *solution of potassium hydroxide*, and *solution of ammonium hydrosulphide*, but soluble in hot *diluted nitric acid*. *Diluted sulphuric acid* produces a white precipitate almost insoluble in *water*, and still less soluble in *diluted sulphuric acid* or in *alcohol* (90 per cent.), but soluble in *solution of ammonium acetate*. *Solution of potassium chromate* produces a yellow precipitate readily soluble in *solution of sodium hydroxide*, in hot *nitric acid*, sparingly soluble in *diluted nitric acid*, insoluble in *acetic acid*." *Br.*

Magnesium.—" *Solution of ammonium carbonate*, in the presence of *solution of ammonium chloride*, produces no precipitate. *Solution of sodium phosphate* in the presence of ammonium salts and *solution of ammonia*, produces a white crystalline precipitate. *Solution of sodium hydroxide* produces a white precipitate, insoluble in excess of the reagent, but soluble in *solution of ammonium chloride*." *Br.*

Mercury.—" Reactions common to Mercurous and Mercuric salts: *Hydrogen sulphide* produces a black precipitate, insoluble in *solution of ammonium hydrosulphide* and in boiling *diluted nitric acid*. Bright *copper* foil immersed in a solution free from excess of nitric acid becomes coated with a deposit of mercury which on rubbing becomes bright; the mercury may be volatilised from the foil by heat and obtained in globules. Reaction characteristic of Mercurous salts: *Hydrochloric acid* produces a white precipitate insoluble in *water*, and blackened by *solution of ammonia*. Reactions characteristic of Mercuric salts: *Solution of sodium hydroxide* produces a yellow precipitate. *Solution of potassium iodide* produces in neutral solutions a scarlet precipitate, soluble in excess of the precipitant, and in a considerable excess of the solution of the mercuric salt." *Br.*

Nitrates.—" *Ferrous sulphate* and *sulphuric acid*, when added to a solution of a nitrate in such a way that the acid forms a stratum below the aqueous solution, produces a brown coloration at the junction of the two liquids. Nitrates liberate red fumes when warmed with *sulphuric acid* and *copper*." *Br.*

Nitrites.—" On the addition, to a solution of a nitrite, of a few drops of *diluted sulphuric acid solution of potassium iodide*, and *mucilage of starch*, a blue colour is produced. *Diluted sulphuric acid* produces red fumes. *Solution of ferrous sulphate* produces a deep-brown colour." *Br.*

Oxalates.—" *Solution of calcium chloride* produces a white precipitate, soluble in *hydrochloric acid* but insoluble in *acetic acid*. *Solution of silver nitrate* produces a white precipitate, soluble in *solution of*

ammonia and in *diluted nitric acid*. Oxalates do not char when heated with *sulphuric acid*, but yield carbon monoxide and carbon dioxide." *Br.*

Phosphates (Ortho-).—"*Solution of silver ammonio-nitrate* produces in solutions of ortho-phosphates a light-yellow precipitate readily soluble in *solution of ammonia* and in cold *diluted nitric acid*. *Solution of magnesium ammonio-sulphate* produces a white crystalline precipitate. Excess of *solution of ammonium molybdate* containing much *nitric acid*, produces, on warming, a yellow precipitate." *Br.*

Potassium.—"*Solution of platinic chloride* produces with moderately strong solutions of potassium chloride (or with other potassium salts if hydrochloric acid be present) a yellow crystalline precipitate, which, upon ignition, leaves a residue of potassium chloride and platinum. Potassium compounds moistened with *hydrochloric acid* when introduced, on platinum wire, into the flame of a Bunsen burner, communicate to the flame a violet coloration." *Br.*

Selenium and Tellurium.—"Selenium and Tellurium may occur in compounds of bismuth. To detect these elements, dissolve the compound in *nitric acid*, add solution of *sodium chloride* or *solution of ammonium chloride*, and dilute freely with *water*. The filtrate from the precipitate, mixed with excess of an aqueous solution of *sodium sulphite*, produces no precipitate or coloration even after twelve hours." *Br.*

Silica.—"Silica, after exposure to a red heat, is insoluble in acids, and is not dissolved in a bead of *purified borax* when heated to fusion in the blowpipe flame. The result of its fusion with *sodium carbonate* is soluble in water, the solution yielding a gelatinous precipitate on the addition of *hydrochloric acid*." *Br.*

Silver.—"*Hydrochloric acid* and other chlorides produce a white curdy precipitate, soluble in *solution of ammonia* but insoluble in *nitric acid*. *Solution of potassium chromate* produces a red precipitate, soluble in *nitric acid*." *Br.*

Sodium.—"Sodium compounds, moistened with *hydrochloric acid*, when introduced, on platinum wire, into the flame of a Bunsen burner, communicate to the flame a yellow coloration." *Br.*

Strontium.—"*Solution of ammonium carbonate* produces a white precipitate, insoluble in *solution of ammonium chloride*. *Solution of ammonium oxalate* produces a white precipitate, insoluble in *acetic acid* but soluble in *hydrochloric acid*. *Solution of potassium chromate* produces a light-yellow precipitate, soluble in *acetic acid*. *Solution of calcium sulphate* produces a white precipitate." *Br.*

Sulphates.—"*Solution of barium chloride* produces a white precipitate insoluble in *hydrochloric acid*." *Br.*

Sulphides.—"The official sulphides, hydrosulphides, and sulphurated compounds evolve hydrogen sulphide when boiled with *hydrochloric acid*." *Br.*

Sulphites.—"*Hydrochloric acid* liberates sulphur dioxide, a colourless gas with a pungent smell of burning sulphur. *Solution of barium chloride* produces a white precipitate soluble in *hydrochloric acid*. Sulphites decolorise *N/10 solution of iodine*." *Br.*

Tartrates.—"Tartrates become charred when heated. *Solution of calcium chloride* added in excess to a solution of a neutral tartrate produces, even when cold, a white granular precipitate, soluble in *acetic acid*. *Solution of silver nitrate* produces a white precipitate, soluble in *solution of ammonia* and in *nitric acid*. The ammoniacal solution, on heating, deposits metallic silver as a mirror on the sides of the test-tube. When to a solution of tartaric acid in *water*, or of a tartrate acidified with *acetic acid*, a drop of *solution of ferrous sulphate*, then a few drops of *solution of hydrogen peroxide*, and finally an excess of *solution of sodium hydroxide* are added, a purple or violet colour is produced." *Br.*

Tellurium. *See* "**Selenium.**"

Thiosulphates.—"*Hydrochloric acid* produces a yellow precipitate and liberates sulphur dioxide, recognisable by its odour. *Solution of barium chloride* produces no precipitate in dilute solutions; on the further addition of *solution of bromine* a white precipitate is produced. Thiosulphates decolorise *N/10 solution of iodine*." *Br.*

Tin.—"Metallic *zinc* placed in a solution of any tin salt acidified with *hydrochloric acid* precipitates the tin in metallic scales or as a grey sponge. The metal, separated from the liquid, is soluble in boiling *hydrochloric acid*, and the solution, which then contains stannous chloride, produces with *T. Sol. of mercuric chloride* a white precipitate which becomes grey if excess of the tin salt is present." *Br.*

Zinc.—"*Solution of ammonium hydrosulphide* produces in neutral, and *hydrogen sulphide* in alkaline solutions, a white precipitate, soluble in *hydrochloric acid* but insoluble in *acetic acid*. *Solution of sodium hydroxide* or *solution of ammonia* produces a white precipitate, soluble in excess of either reagent. *Solution of potassium ferrocyanide* produces a white precipitate, insoluble in *diluted hydrochloric acid*." *Br.*

APPENDIX V. Br.

Quantitative Limit-test For Lead. Br.

Apparatus

(All glass apparatus used must be lead-free.)

Nessler Glasses.—"Thin, and of lead-free glass. About 150 millimetres long, and of such diameter that the mark indicating a content of 50 millilitres is at the height of 100 millimetres from the base." *Br.*

Solutions and Reagents

The special solutions and reagents for the Quantitative Limit-test for lead are distinguished by the letters "Pb T."

Strong Solution of Lead Pb T.—"Dissolve 0.16 gramme of Lead Nitrate in Distilled Water, adding 50 millilitres of Nitric Acid, and dilute with Distilled Water to 100 millilitres. This solution contains 0.001 gramme of lead in 1 millilitre." *Br.*

Dilute Solution of Lead Pb T.—"Dilute 1 millilitre of the Strong Solution of Lead Pb T., measured from a burette, with Distilled Water so that the resulting solution measures 100 millilitres. This solution contains 0.00001 gramme of lead in 1 millilitre." *Br.*

Solution of Potassium Cyanide Pb T.—"Dissolve 10 grammes of Potassium Cyanide in Distilled

Water, add 2 millilitres of Solution of Hydrogen Peroxide and make up to 100 millilitres with Distilled Water. This solution after being allowed to stand, when tested by the quantitative limit-test for lead, gives no colour with the Dilute Solution of Lead Pb T." *Br.*

Solution of Sodium Sulphide Pb T.—"Dissolve 10 grammes of Sodium Sulphide in Distilled Water and make up to 100 millilitres with Distilled Water." *Br.*

Mode of Testing (General)

"Two solutions of the substance under examination are made in hot Distilled Water: (1) The primary solution containing 12 grammes of the substance. (2) The auxiliary solution containing 2 grammes of the substance. Each solution is filtered (if necessary), made alkaline with *solution of ammonia*, and treated with 1 millilitre of the solution of potassium cyanide Pb T. If the colours of the solutions differ much, the difference may be rectified by the cautious addition of a highly diluted solution of burnt sugar. Then, by the method of trial and error (well known in water analysis as "Nesslerizing"), is determined the quantity of the dilute solution of lead Pb T. which must be added to the auxiliary solution, in order that there may be equal colorations produced upon the addition of 2 drops of the solution of sodium sulphide Pb T. to both the primary and the auxiliary solution, after dilution to the 50 millilitre mark. In these circumstances, each millilitre of the dilute solution of lead Pb T. required corresponds to 1 part per million of lead in the substance examined. The colorations may be viewed by light reflected from a horizontal white tile through the Nessler glasses inclined at an angle to the observer." *Br.*

Note.—" In some cases, 7 or 4 grammes only are used in the primary solution. In these cases each millilitre of the dilute solution of lead Pb T. required will represent 2 or 5 parts per million of lead respectively." *Br.*

Substance.	Primary Solution of Substance: Grammes employed.	Auxiliary Solution of Substance: Grammes employed.	Dilute Solution of Lead PbT.: Millilitres employed.	Limit of Lead: Parts per Million.

APPENDIX VI. Br.

Quantitative Limit-test For Arsenic. Br.

Note.—" In the quantitative limit-test for arsenic the amount of arsenic present per million is calculated as arsenious oxide, As_4O_6." *Br.*

Apparatus.—" A wide-mouthed bottle capable of holding about 120 millilitres and fitted with a rubber cork through which passes a glass tube. The latter, made from ordinary soft glass tubing, has a total length of 200 millimetres and an internal diameter of 5 millimetres (external diameter 7 millimetres) and is open at both ends. The upper end is slightly widened to a diameter of 8 millimetres, while the lower end is drawn out to about 1 millimetre in diameter, and a hole about 2 millimetres in diameter blown in the side of the tube where it is constricted." *Br.*

Lead Papers.—"Lead papers are pieces of thin white filter paper 100 millimetres × 40 millimetres, soaked in *solution of lead acetate* and dried." *Br.*

Mercuric Chloride Papers.—"Mercuric chloride papers are circles of smooth white filter paper 5.5 centimetres in diameter soaked in a saturated aqueous solution of mercuric chloride and dried." *Br.*

Note.—" The mercuric chloride papers should be stored in a stoppered bottle in the dark. Mercuric chloride papers that have been exposed to sunlight afford a lighter-coloured stain when employed in an arsenic test.

Reagents

The special reagents for the quantitative limit-test for arsenic are distinguished by the letters "As T."

Brominated Hydrochloric Acid As T.—"Solution of Bromine As T., 1 millilitre; Hydrochloric Acid As T. sufficient to produce 100 millilitres. Mix." *Br.*

Calcium Hydroxide As T.—"10 grammes tested as described under 'Calcii Hydras,' page 1742, give no visible stain." *Br.*

Citric Acid As T.—"10 grammes tested as described under 'Acidum Aceticum,' page 1740, give no visible stain." *Br.*

Hydrochloric Acid As T.—"Contains not more than 0.1 part per million of arsenic, as shown by the *Control Test*, and is free from iron." *Br.*

Nitric Acid As T.—"10 millilitres treated as described under 'Acidum Nitricum,' page 1741, give no visible stain." *Br.*

Potassium Chlorate As T.—"Five grammes tested as described under 'Potassii Chloras,' page 1744, give no visible stain." *Br.*

Solution of Arsenic As T.—"Hydrochloric Solution of Arsenic, 1 millilitre; Distilled Water sufficient to produce 1000 millilitres. Mix. This solution must be freshly prepared. 1 millilitre contains 0.00001 gramme (=one-hundredth of one milligram) of arsenic." *Br.*

Solution of Bromine As T.—"Bromine, 30 grammes; Potassium Bromide, 30 grammes; Distilled Water sufficient to produce 100 millilitres. Dissolve. It contains not more than 1 part per million of arsenic as shown by the *Control Test*." *Br.*

Solution of Stannous Chloride As T.—"It is prepared from the Solution of Stannous Chloride, Appendix II, page 1734, by adding an equal volume of Hydrochloric Acid, boiling down to the original bulk and filtering. It contains not more than 1 part per million of arsenic, as shown by the *Control Test*." *Br.*

Stannated Hydrochloric Acid As T.—"Solution of Stannous Chloride As T., 1 millilitre; Hydrochloric Acid As T. sufficient to produce 100 millilitres. Mix." *Br.*

Sulphuric Acid As T.—"Ten grammes, tested as described under 'Acidum Sulphuricum,' page 1741, but omitting the stannated hydrochloric acid As T. and adding 0.2 millilitre of solution of stannous chloride As T., give no visible stain." *Br.*

Zinc As T.—"Zinc As T. is granulated zinc which conforms to the arsenic requirement involved in the *Control Test*, and is free from iron." *Br.*

Method of Performing the Quantitative Test for Arsenic

"By a variable method of procedure suitable to the particular needs of each case there is prepared from the substance to be tested a solution, which may or may not contain the substance to be treated, but in every case contains the whole of the arsenic (if any) originally in that substance. It is this solution—hereinafter referred to as 'the solution to be examined'—which is introduced into the actual test." *Br.*

General Test.—"A strip of lead paper is rolled up and placed in the glass tube so that the upper end is not less than 2 centimetres below the top of the tube. A piece of the mercuric chloride paper is now placed over the top of the tube and secured by means of a rubber ring. The tube is inserted in the rubber cork. The solution to be examined, prepared as specified, is placed in the wide-mouthed bottle and 10 grammes of zinc As T. added. The rubber cork with glass tube attached is quickly placed in position so that the lower end of the tube is clear above the surface of the liquid, and the hole in the constricted portion of the tube is clear below the bottom of the cork. The action should be allowed to proceed for thirty to forty minutes, the mercuric chloride paper not being exposed to strong sunlight. The yellow stain which is produced on the mercuric chloride paper if arsenic be present is compared, by daylight, with stains produced by operating in a similar manner with known quantities of the solution of arsenic As T. The comparison of the stains should be made at the completion of the test and those used for comparison should be freshly prepared. The stains fade upon keeping." *Br.*

Note.—"The action may be accelerated by standing the apparatus on a hot plate, care being taken that the mercuric chloride paper remains quite dry throughout the duration of the test.

Standard Stain.—"Prepare a solution by adding to 50 millilitres of hot *water*, 10 millilitres of stannated hydrochloric acid As T. and 1 millilitre of solution of arsenic As T. The resulting solution when treated as described in the 'General Test' will yield a stain on the mercuric chloride paper hereinafter referred to as the 'Standard Stain.'" *Br.*

Control Tests for Reagents As T.

Hydrochloric Acid As T.—"To 50 millilitres of the hydrochloric acid to be tested add 0.2 millilitre of solution of bromine As T., evaporate on a water-bath until reduced to 16 millilitres, add 50 millilitres of hot *water* and 5 drops of solution of stannous chloride As T. and with this solution carry out the 'General Test' described above. The stain produced on the mercuric chloride paper is not deeper than that given by 10 millilitres of the same hydrochloric acid with 5 drops of solution of stannous chloride As T., 0.4 millilitre of solution of arsenic As T. and 50 millilitres of hot *water*, showing that the proportion of arsenic present does not exceed 0.1 part per million." *Br.*

Solution of Bromine As T.—"Evaporate 10 millilitres of the solution of bromine on a water-bath nearly to dryness, add 50 millilitres of hot *water*, 10 millilitres of hydrochloric acid As T., and sufficient solution of stannous chloride As T. to reduce the remaining bromine, and with this solution carry out the 'General Test' described above. The stain produced on the mercuric chloride paper is not deeper than the Standard Stain, showing that the proportion of arsenic present does not exceed 1 part per million." *Br.*

Solution of Stannous Chloride As T.—"To 10 millilitres of the solution of stannous chloride add 6 millilitres of *water* and 10 millilitres of hydrochloric acid As T., and distil 16 millilitres. To the distillate add 50 millilitres of hot *water* and a few drops of solution of stannous chloride As T. and with this solution carry out the 'General Test' described above. The stain produced on the mercuric chloride paper is not deeper than the Standard Stain, showing that the proportion of arsenic present does not exceed 1 part per million." *Br.*

Zinc As T.—"Add 10 millilitres of stannated hydrochloric acid As T., to 50 millilitres of hot *water*, and with this solution and 10 grammes of zinc As T. proceed as with the 'General Test,' but allow the action to continue for one hour. No visible stain is produced on the mercuric chloride paper (limit of arsenic in the zinc)." *Br.*

The following Table shows the varying methods of preparing the "solution to be examined." The quantities are so arranged that, when tested according to the "General Test" described above, the stain produced on the mercuric chloride paper is not deeper than the Standard Stain, showing that the proportion of arsenic present does not exceed the permissible limit.

Substance.	Solution to be examined.	Limit of Arsenic: Parts per million.
Acidum Aceticum	5 grammes in 50 millilitres of hot *water*, adding 10 millilitres of stannated hydrochloric acid As T.	2
Acidum Acetylsalicylicum	5 grammes made into a paste in a porcelain dish with 2 grammes of calcium hydroxide As T. and 5 millilitres of *water*, drying and gently igniting, dissolving residue in 16 millilitres of brominated hydrochloric acid As T. and 45 millilitres of hot *water*, and finally removing excess of bromine by a few drops of solution of stannous chloride As T.	2
Acidum Benzoicum	5 grammes treated as described under "Acidum Acetylsalicylicum."	2
Acidum Boricum	2 grammes with 4 grammes of citric acid As T. in 50 millilitres of hot *water*, adding 10 millilitres of stannated hydrochloric acid As T.	5

Substance.	Solution to be examined.	Limit of Arsenic: Parts per million.
Acidum Citricum	7 grammes treated as described under "Acidum Aceticum."	1.4
Acidum Hydriodicum Dilutum	2 grammes with 50 millilitres of hot *water*, adding 0.5 millilitre of solution of bromine As T. and 10 millilitres of hydrochloric acid As T., allowing it to stand for five minutes, and removing excess of bromine by a few drops of solution of stannous chloride As T.	5
Acidum Hydrobromicum Dilutum	2 grammes treated as described under "Acidum Aceticum."	5
Acidum Hydrochloricum	2 grammes with 50 millilitres of hot *water* and 8 millilitres of stannated hydrochloric acid As T.	5
Acidum Lacticum	2 grammes treated as described under "Acidum Aceticum."	5
Acidum Nitricum	2 grammes heated in a porcelain dish with 2 millilitres of sulphuric acid As T. until white fumes are evolved, then cooling, adding 2 millilitres of *water*, again heating until white fumes are evolved, again cooling and adding to the residue 50 millilitres of hot *water* and 10 millilitres of stannated hydrochloric acid As T.	5
Acidum Phosphoricum Concentratum	2 grammes treated as described under "Acidum Aceticum."	5
Acidum Salicylicum	5 grammes treated as described under "Acidum Acetylsalicylicum."	2
Acidum Sulphuricum	2 grammes mixed with 10 millilitres of *water*, adding 40 millilitres of hot *water* and 8 millilitres of stannated hydrochloric acid As T.	5
Acidum Sulphurosum	2 grammes mixed in the cold with 0.5 gramme of potassium chlorate As T. and 11 millilitres of hydrochloric acid As T., warming to expel excess of chlorine, then adding 50 millilitres of hot *water* and a few drops of solution of stannous chloride As T.	5
Acidum Tartaricum	7 grammes treated as described under "Acidum Aceticum."	1.4
Alumen Purificatum	2 grammes treated as described under "Acidum Aceticum."	5
Ammonii Benzoas	5 grammes treated as described under "Acidum Acetylsalicylicum."	2
Ammonii Bromidum	2 grammes in 50 millilitres of hot *water*, adding 12 millilitres of stannated hydrochloric acid As T.	5
Ammonii Carbonas	5 grammes in 50 millilitres of hot *water*, boiled gently until the greater part of the ammonium carbonate is volatilised, then adding 15 millilitres of brominated hydrochloric acid As T. and removing excess of bromine by a few drops of solution of stannous chloride As T.	2
Ammonii Chloridum	2 grammes treated as described under "Acidum Aceticum."	5
Antimonium Sulphuratum	0.01 gramme dissolved by boiling in a small flask with 0.2 gramme of calcium hydroxide As T. and 5 millilitres of *water*, then adding 2 millilitres of solution of bromine As T. and again gently boiling, then adding 17 millilitres of hydrochloric acid As T. and 5 millilitres of *water* and boiling until most of the bromine is volatilised, the last traces being removed by adding a slight excess of solution of stannous chloride As T., connecting to a condenser and distilling 20 millilitres, then washing the condenser and flask, returning the distillate to the flask, adding 1 drop of solution of stannous chloride As T. and redistilling 16 millilitres, then adding to the distillate 45 millilitres of hot *water* and a few drops of solution of stannous chloride As T.	1000

Substance.	Solution to be examined.	Limit of Arsenic: Parts per million.
Bismuthi Carbonas	5 grammes dissolved in a small flask in 5 millilitres of *water* and 20 millilitres of brominated hydrochloric acid As T., removing excess of bromine by a few drops of solution of stannous chloride As T., connecting to a condenser and distilling 18 millilitres, then adding to the distillate 40 millilitres of hot *water* and 3 drops of solution of stannous chloride As T.	2
Bismuthi Salicylas	5 grammes made into a paste in a porcelain dish with 1 gramme of calcium hydroxide As T. and 5 millilitres of *water*, drying and gently igniting, dissolving the residue in 20 millilitres of brominated hydrochloric acid As T. and 10 millilitres of *water*, transferring to a small flask and adding sufficient solution of stannous chloride As T. to remove the excess of bromine, connecting to a condenser and distilling 20 millilitres, then adding to the distillate 40 millilitres of hot *water* and 3 drops of solution of stannous chloride As T.	2
Bismuthi Subnitras	5 grammes heated in a porcelain dish with 2 millilitres of sulphuric acid As T. until white fumes are evolved, cooling, adding 5 millilitres of *water* and again heating until white fumes are evolved, dissolving the residue when cold in 20 millilitres of *water* and 10 millilitres of stannated hydrochloric acid As T., transferring to a small flask, connecting to a condenser and distilling 20 millilitres, adding to the distillate a little solution of bromine As T. to oxidise any sulphurous acid, removing excess of bromine by a few drops of solution of stannous chloride As T., and adding 40 millilitres of hot *water*.	2
Borax Purificatus	2 grammes with 4 grammes of citric acid As T. in 50 millilitres of hot *water*, adding 12 millilitres of stannated hydrochloric acid As T.	5
Calcii Carbonas Præcipitatus	2 grammes in 14 millilitres of brominated hydrochloric acid As T. and 45 millilitres of hot *water*, removing excess of bromine by a few drops of solution of stannous chloride As T.	5
Calcii Chloridum	2 grammes treated as described under " Acidum Aceticum."	5
Calcii Hydras	2 grammes in 16 millilitres of brominated hydrochloric acid As T. and 45 millilitres of hot *water*, removing excess of bromine by a few drops of solution of stannous chloride As T.	5
Calcii Hypophosphis	2 grammes mixed in the cold with 2 grammes of potassium chlorate and 18 millilitres of hydrochloric acid As T., then warming to expel excess of chlorine, adding 40 millilitres of hot *water* and a few drops of solution of stannous chloride As T.	5
Calcii Lactas	2 grammes treated as described under " Ammonii Bromidum."	5
Calcii Phosphas	2 grammes in 50 millilitres of hot *water* and 14 millilitres of stannated hydrochloric acid As T.	5
Calx	2 grammes in 18 millilitres of brominated hydrochloric acid As T. and 40 millilitres of *water*, removing excess of bromine by a few drops of solution of stannous chloride As T.	5
Creta Præparata	2 grammes treated as described under " Calcii Carbonas Præcipitatus."	5
Cupri Sulphas	1 gramme dissolved in a small flask, with 10 millilitres of *water* and 15 millilitres of hydrochloric acid As T., adding 5 drops of solution of stannous chloride As T., connecting to a condenser and distilling 20 millilitres, adding a little solution of bromine As T. to the distillate to oxidise any sulphurous acid, removing excess of bromine by a few drops of solution of stannous chloride As T., finally adding 40 millilitres of hot *water*.	10

Substance.	Solution to be examined.	Limit of Arsenic: Parts per million.
Ferri Carbonas Saccharatus	2 grammes made into a paste with 1 gramme of calcium hydroxide As T. and 2 millilitres of *water* in a porcelain dish, drying and gently igniting, dissolving the residue in 20 millilitres of brominated hydrochloric acid As T. and 10 millilitres of *water*, transferring to a small flask, adding solution of stannous chloride As T. until the yellow colour disappears, then connecting to a condenser and distilling 24 millilitres, finally adding to the distillate 35 millilitres of hot *water* and 3 drops of solution of stannous chloride As T.	5
Ferri et Ammonii Citras	2 grammes treated as described under "Ferri Carbonas Saccharatus."	5
Ferri et Potassii Tartras	2 grammes treated as described under "Ferri Carbonas Saccharatus."	5
Ferri et Quininæ Citras	2 grammes treated as described under "Ferri Carbonas Saccharatus."	5
Ferri Phosphas Saccharatus	2 grammes treated as described under "Ferri Carbonas Saccharatus."	5
Ferri Sulphas	5 grammes dissolved in a small flask, with 10 millilitres of *water* and 15 millilitres of hydrochloric acid As T., adding solution of stannous chloride As T. until the yellow colour disappears, connecting to a condenser and distilling 20 millilitres, adding a little solution of bromine As T. to the distillate to oxidise any sulphurous acid, removing excess of bromine by a few drops of solution of stannous chloride As T., and finally adding 40 millilitres of hot *water*.	2
Ferri Sulphas Exsiccatus	2 grammes treated as described under "Ferri Sulphas."	5
Ferrum	0.05 gramme mixed in a small flask with 0.1 gramme of potassium chlorate As T. and 7 millilitres of *water*, adding 11 millilitres of hydrochloric acid As T. and, when the reaction has ceased and all the iron is dissolved, boiling gently to expel chlorine, then adding solution of stannous chloride As T. until the yellow colour disappears, connecting to a condenser and distilling 14 millilitres, finally adding to the distillate 50 millilitres of hot *water* and a few drops of solution of stannous chloride As T.	200
Ferrum Redactum	0.05 gramme treated as described under "Ferrum."	200
Glucosum	5 grammes treated as described under "Acidum Hydriodicum Dilutum."	2
Glycerinum	2.5 grammes treated as described under "Acidum Aceticum."	4
Liquor Ammoniæ Fortis	20 grammes evaporated on a water-bath until reduced to 5 millilitres, adding 40 millilitres of *water* and 15 millilitres of brominated hydrochloric acid As T., and removing excess of bromine by a few drops of solution of stannous chloride As T.	0.5
Liquor Ferri Perchloridi Fortis	1 gramme heated in a porcelain dish with 1 millilitre of sulphuric acid As T. until white fumes are evolved, cooling, adding an equal volume of *water* and again heating until white fumes are evolved, dissolving the residue in 10 millilitres of *water* and 15 millilitres of hydrochloric acid As T., transferring to a small flask, adding solution of stannous chloride As T. until the yellow colour disappears, connecting to a condenser and distilling 20 millilitres, adding to the distillate a little solution of bromine As T. to oxidise any sulphurous acid, removing excess of bromine by a few drops of solution of stannous chloride As T., and then adding 40 millilitres of hot *water*.	10
Liquor Ferri Persulphatis	2 grammes treated as described under "Liquor Ferri Perchloridi Fortis."	5

Substance.	Solution to be examined.	Limit of Arsenic: Parts per million.
Liquor Magnesii Bicarbonatis	50 millilitres with 13 millilitres of brominated hydrochloric acid As T., removing excess of bromine by a few drops of solution of stannous chloride As T.	0.2
Lithii Carbonas	2 grammes treated as described under "Calcii Hydras."	5
Lithii Citras	5 grammes in 45 millilitres of hot *water*, adding 15 millilitres of stannated hydrochloric acid As T.	2
Magnesia Levis	2 grammes with 40 millilitres of *water* and 20 millilitres of brominated hydrochloric acid As T., removing excess of bromine by a few drops of solution of stannous chloride As T.	5
Magnesia Ponderosa	2 grammes treated as described under "Magnesia Levis."	5
Magnesii Carbonas Levis	2 grammes in 45 millilitres of hot *water* and 15 millilitres of brominated hydrochloric acid As T., removing excess of bromine by a few drops of solution of stannous chloride As T.	5
Magnesii Carbonas Ponderosus	2 grammes treated as described under "Magnesii Carbonas Levis."	5
Magnesii Sulphas	2 grammes treated as described under "Acidum Aceticum."	5
Potassii Acetas	2 grammes treated as described under "Ammonii Bromidum."	5
Potassii Bicarbonas	2 grammes in 50 millilitres of hot *water*, adding 12 millilitres of brominated hydrochloric acid As T., removing excess of bromine by a few drops of solution of stannous chloride As T.	5
Potassii Bromidum	2 grammes treated as described under "Ammonii Bromidum."	5
Potassii Carbonas	5 grammes in 50 millilitres of hot *water*, adding 16 millilitres of brominated hydrochloric acid As T., removing excess of bromine by a few drops of solution of stannous chloride As T.	2
Potassii Chloras	2 grammes mixed in the cold with 10 millilitres of *water* and 20 millilitres of hydrochloric acid As T. and, when the reaction is complete, warming to expel chlorine, then adding a few drops of solution of stannous chloride As T. and 30 millilitres of hot *water*.	5
Potassii Citras	5 grammes treated as described under "Lithii Citras."	2
Potassii Iodidum	2 grammes treated as described under "Ammonii Bromidum."	5
Potassii Nitras	2 grammes heated in a porcelain dish with 2 millilitres of sulphuric acid As T. and 5 millilitres of *water* until white fumes are evolved, cooling, adding 3 millilitres of *water* and again heating until white fumes are evolved, finally cooling and adding to the residue 50 millilitres of hot *water* and 10 millilitres of stannated hydrochloric acid As T.	5
Potassii Sulphas	2 grammes treated as described under "Acidum Aceticum."	5
Potassii Tartras	5 grammes treated as described under "Calcii Phosphas."	2
Potassii Tartras Acidus	5 grammes in 50 millilitres of hot *water* and 13 millilitres of brominated hydrochloric acid As T., removing excess of bromine by a few drops of solution of stannous chloride As T.	2
Sodii Benzoas	5 grammes gently heated in a porcelain dish, until inflammable vapors cease to be evolved, dissolving the residue (ignoring any carbon) in 14 millilitres of brominated hydrochloric acid As T. and 50 millilitres of hot *water* and removing excess of bromine by a few drops of solution of stannous chloride As T.	2
Sodii Bicarbonas	5 grammes treated as described under "Potassii Carbonas."	2
Sodii Bromidum	2 grammes treated as described under "Ammonii Bromidum."	5

Substance.	Solution to be examined.	Limit of Arsenic: Parts per million.
Sodii Carbonas	5 grammes in 50 millilitres of hot *water*, adding 14 millilitres of brominated hydrochloric acid As T. and removing excess of bromine by a few drops of solution of stannous chloride As T.	2
Sodii Carbonas Exsiccatus	2 grammes treated as described under "Sodii Carbonas."	5
Sodii Chloridum	5 grammes treated as described under "Acidum Aceticum."	2
Sodii et Potassii Tartras	5 grammes treated as described under "Calcii Phosphas."	2
Sodii Hypophosphis	2 grammes treated as described under "Calcii Hypophosphis."	5
Sodii Iodidum	2 grammes in 50 millilitres of hot *water*, adding 11 millilitres of stannated hydrochloric acid As T.	5
Sodii Nitris	2 grammes treated as described under "Potassii Nitras."	5
Sodii Phosphas	2 grammes treated as described under "Acidum Aceticum."	5
Sodii Phosphas Acidus	5 grammes treated as described under "Acidum Aceticum."	2
Sodii Salicylas	5 grammes treated as described under "Sodii Benzoas."	2
Sodii Sulphas	5 grammes treated as described under "Acidum Aceticum."	2
Sodii Sulphis	2 grammes with 0.5 gramme of potassium chlorate As T. in 5 millilitres of warm *water*, adding 12 millilitres of hydrochloric acid As T., then warming to expel excess of chlorine and adding 45 millilitres of hot *water* and a few drops of solution of stannous chloride As T.	5
Strontii Bromidum	2 grammes treated as described under "Ammonii Bromidum."	5
Sulphur Præcipitatum	2 grammes digested for one hour on a water-bath with 50 millilitres of *water* and 5 millilitres of solution of ammonia, filtering and evaporating the filtrate to low bulk, adding 10 millilitres of nitric acid As T. and boiling to oxidise any sulphur, then adding 2 millilitres of sulphuric acid As T. and heating until white fumes are evolved, cooling, adding 2 millilitres of *water* and again heating until white fumes are evolved, finally adding 50 millilitres of hot *water* and 10 millilitres of stannated hydrochloric acid As T.	
Sulphur Sublimatum	2 grammes treated as described under "Sulphur Præcipitatum."	5
Zinci Acetas	2 grammes treated as described under "Ammonii Bromidum."	5
Zinci Carbonas	1 gramme treated as described under "Potassii Carbonas."	10
Zinci Chloridum	2 grammes treated as described under "Acidum Aceticum."	5
Zinci Oxidum	1 gramme treated as described under "Potassii Carbonas."	10
Zinci Sulphas	2 grammes treated as described under "Acidum Aceticum."	5
Zinci Valerianas	2 grammes made into a paste in a porcelain dish with 2 grammes of calcium hydroxide As T. and 5 millilitres of *water*, drying and gently igniting, then dissolving the residue in 18 millilitres of brominated hydrochloric acid As T. and 40 millilitres of hot *water* and removing excess of bromine by a few drops of solution of stannous chloride As T.	5

APPENDIX VII. Br.

Determination of the Acid Value of Fixed Oils, Fats, Waxes, and Resins. Br.

"The acid value of a fixed oil, fat, or wax (the number of milligrams of potassium hydroxide required to neutralise the free acid in 1 gramme of the substance) is determined as follows:—Mix 10 grammes of the substance with 50 millilitres of *alcohol* (90 per cent.), previously neutralised with *solution* of *potassium hydroxide*, add 1 millilitre of *solution of phenolphthalein*, heat until the fat or wax is melted and titrate with

N/10 solution of potassium hydroxide, shaking constantly. Note the number of millilitres required (*a*). Calculate the acid value from the following formula:—

$$\text{"Acid value} = \frac{a \times 0.0056 \times 1000}{\text{weight (in grammes) of substance taken}}$$

"The acid value of a resin is determined by dissolving from 1 to 5 grammes of the substance in 50 millilitres of *alcohol* (90 per cent.), previously neutralised, and titrating and calculating as above directed." *Br.*

Determination of the Saponification Value of Fixed Oils, Fats, Waxes, and Resins. Br.

"The saponification value of a fixed oil, fat, wax, or resin (the number of milligrams of potassium hydroxide required for the complete saponification of 1 gramme of the substance) is determined as follows:—Dissolve 40 grammes of *potassium hydroxide* in 1000 millilitres of *alcohol* (90 per cent.), previously neutralised; allow the solution to stand for twenty-four hours and filter. Weigh from 1.5 to 2 grammes of the substance in a flask having a capacity of about 200 millilitres; add 25 millilitres of the alcoholic solution of potassium hydroxide, attach a reflux condenser and heat on a water-bath for thirty minutes; add 1 millilitre of *solution of phenolphthalein* and titrate the excess of alkali with *N/2 solution of hydrochloric acid*. Note the number of millilitres required (*a*). At the same time treat 25 millilitres of the alcoholic solution of potassium hydroxide in a similar manner. Note the number of millilitres required (*b*). Calculate the saponification value from the following formula:—

$$\text{"Saponification value} = \frac{(b-a) \times 0.028 \times 1000}{\text{weight (in grammes) of substance taken}}\text{"}$$ *Br.*

Determination of the Iodine Value of Fixed Oils and Fats. Br.

"The iodine value of a fixed oil or fat (the proportional weight of iodine absorbed by 100 parts by weight of the oil or fat under the conditions specified) is determined as follows:—

Solution to be Prepared.—Iodine Solution.—"Dissolve 13 grammes of iodine in 1000 millilitres of *glacial acetic acid*. Titrate the solution with *N/10 solution of sodium thiosulphate*, note the proportion required and pass *chlorine*, washed and dried, through the remainder of the iodine solution until this proportion is exactly doubled. Keep the solution in a stoppered amber bottle in a cool, dark place."

Weight of Substance to be Taken.—"Lard, Suet, and Oil of Theobroma 0.8 to 1.0 gramme; Almond Oil, Castor Oil, and Olive Oil, 0.3 to 0.4 gramme; Cod-liver Oil, and Linseed Oil 0.15 to 0.18 gramme.

Time to be Allowed for Absorption.—"Lard, Suet, and Oil of Theobroma, Almond Oil, Castor Oil, and Olive Oil, 1 hour; Cod-liver Oil and Linseed Oil, 2 hours."

Method of Procedure.—"Place the specified weight of oil or fat in a stoppered bottle having a capacity of 800 millilitres, add 10 millilitres of *carbon tetrachloride* and dissolve. Add 25 millilitres of the iodine solution, insert the stopper, previously moistened with *solution of potassium iodide*, and keep in a dark place at a temperature of about 17° for the specified time. Then add 20 millilitres of *solution of potassium iodide* and 500 millilitres of *water*. Shake, and titrate with *N/10 solution of sodium thiosulphate*, using *mucilage of starch* as indicator. Note the number of millilitres required (*a*). At the same time treat 25 millilitres of the solution of iodine in a similar manner and note the number of millilitres of *N/10 solution of sodium thiosulphate* required (*b*). Calculate the iodine value from the following formula:—

$$\text{"Iodine value} = \frac{(b-a) \times 0.01269 \times 100}{\text{weight (in grammes) of oil or fat taken}}\text{"}$$ *Br.*

Determination of the Unsaponifiable Matter in Fixed Oils and Fats. Br.

"The percentage of unsaponifiable matter in a fixed oil or fat is determined as follows:—Boil 5 grammes of the oil or fat with 50 millilitres of *N/1 alcoholic solution of potassium hydroxide* in a flask provided with a reflux condenser on a water-bath for thirty minutes. Transfer the contents of the flask to a porcelain dish and evaporate the alcohol on a water-bath. Dissolve the resulting soap in about 100 millilitres of hot water, cool and transfer to a separator. Add 50 millilitres of *ether*, mix thoroughly and allow to separate. Transfer the soap solution to another separator and again extract with 50 millilitres of *ether*. Mix the ethereal solutions, wash with three portions, each of 20 millilitres, of *water*, transfer to a tared flask, evaporate the ether, dry the residue at 100° C. (212° F.) and weigh. The weight (in grammes) of the residue multiplied by 20 gives the percentage of unsaponifiable matter." *Br.*

Determination of the Esters in Volatile Oils. Br.

"The percentage of esters present in a volatile oil is determined as follows:—Dissolve from 2 to 5 grammes of the oil in 25 millilitres of alcohol (90 per cent.) and neutralise the solution, if necessary, with *N/1 alcoholic solution of potassium hydroxide*. Then add 25 millilitres of *N/1 alcoholic solution of potassium hydroxide*, boil in a flask provided with a reflux condenser on a water-bath for one hour, and titrate the excess of alkali with *N/1 solution of sulphuric acid*. Note the number of millilitres required (*a*). At the same time treat 25 millilitres of *alcohol* (90 per cent.) in a similar manner and note the number of millilitres of acid required (*b*). Calculate the percentage of esters in the oil from the following formula:—

$$\text{"Percentage of esters} = \frac{(b-a) \times \text{molecular weight of ester}}{\text{weight (in grammes) of oil taken} \times 10}\text{"}$$ *Br.*

Determination of the Alcohols in Volatile Oils. Br.

"The percentage of alcohols present in a volatile oil is determined as follows:—Heat 10 millilitres of the oil with 10 millilitres of *acetic anhydride* and 2 grammes of *anhydrous sodium acetate* in an acetylation flask for two hours; add 100 millilitres of *water*, transfer to a separator and, after separation, remove the aqueous layer and wash the oily layer free from acidity with successive quantities, each of 100 millilitres of *water*, thoroughly shaking and allowing to separate each time. Dry the acetylated oil with *anhydrous sodium sulphate* and filter. Then treat from 2 to 5 grammes of the acetylated oil according to the process for the determination of the esters present in volatile oils. Calculate the percentage of alcohols present in the oil from the following formula:—

"**Percentage of alcohols** = $\frac{\frac{1}{10} \times (b-a) \times \text{molecular weight of the alcohol}}{\text{weight (in grammes) of acetylated oil taken}—0.042\ (b-a)}$ " *Br.*

Alkaloidal Assays: Limit of Error. Br.

"Successive assays of the same substance may yield numerical results varying within narrow limits, which are taken to be the range of 'error.' When an average of successive assays shows a deviation from the prescribed standard greater or less than the 'limit of error,' the preparation examined does not conform to the requirements of the British Pharmacopœia." *Br.*

APPENDIX VIII. Br.

Determination of Melting Points. Br.

"Prepare some thin-walled glass tubes having an internal diameter of about one millimetre by heating thick-walled, soft glass tubing in a blow-pipe flame, drawing out the heated portion until it has the required diameter, then allowing a small flame to play against the middle of this tube so as to make and seal two tubes which are finally to be cut off to suitable lengths; these tubes should be freshly made; if stored they should be carefully protected from moisture.

"Dry a very small quantity of the powdered substance at 100° C. (212° F.) for fifteen minutes; transfer a portion to one of these tubes, shaking the powder down to the sealed extremity. Attach the tube to a thermometer so that the substance is near the middle of the bulb. Heat a suitable liquid, such as *sulphuric acid*, to which *nitric acid* in the proportion of about 4 drops to 100 millilitres has been added, in a beaker or boiling tube about 3 centimetres in diameter, to about 5° below the expected melting point of the substance; this point, if not known, being determined by a preliminary experiment. Then introduce the thermometer with the attached tube, and slowly heat, efficiently stirring, and note the temperature at which the substance first shows visible change; this temperature is regarded as the uncorrected melting point of the substance. The whole of the mercury column of the thermometer should be immersed in the liquid, but as this is seldom practicable the following correction is to be applied:—

"To the thermometer attach a second thermometer in such a position that its bulb is near the middle of the emergent column of mercury, and observe thereby the mean temperature of the column. Calculate the corrected melting point of the substance from the following formula:—

"Corrected melting point = T + 0.000143 (T − t) N, in which T = the uncorrected melting point; t = the mean temperature of the emergent column; N = the number of scale degrees in the emergent column.

"The melting point of solid fats, fatty acids, and waxes is determined by running a small quantity of the melted substance into an unsealed melting point tube, allowing it to cool for twenty-four hours, and then, using *water* in the place of sulphuric acid, determining in the manner described the temperature at which the substance becomes a clear liquid; this temperature is to be taken as the uncorrected melting point." *Br.*

Determination of Boiling Points. Br.

"Place the liquid under examination in a distillation flask having a side tube for conveying the vapour to a condenser, while a thermometer passes through a cork inserted in the neck. The bulb of the thermometer should be opposite the entrance of the side tube, and not immersed in the liquid or exposed to splashes of it, and the whole of the column of mercury should, if possible, be surrounded by the vapour; the temperature is read off as soon as the liquid is distilling freely. If any considerable length of the column of mercury is not surrounded by the vapour, the mean temperature of the emergent column should be ascertained as directed under the 'Determination of Melting Points,' and the like correction applied." *Br.*

Determination of Refractive Indices. Br.

"The refractive index of a substance should be determined in a suitable apparatus as nearly as possible at the temperature specified. Should the temperature be either above or below the specified temperature, the following correction is to be applied:—For each degree below the specified temperature subtract 0.00038 from the observed refractive index; for each degree above the specified temperature add 0.00038." *Br.*

Determination of Optical Rotation. Br.

"The optical rotation, unless otherwise specified, is the angle through which the plane of polarisation is turned when a layer of the liquid substance one decimetre in thickness and at a temperature of 20° C. (68° F.) is examined by polarised sodium light.

"The specific rotation of a substance in solution may be calculated from the formula $\frac{a \times 100}{l \times c}$, where

a is the observed optical rotation, l the thickness in decimetres of the layer examined, and c the number of grammes of substance contained in 100 millilitres of the solution." *Br.*

Determination of Specific Gravity. Br.

"The specific gravity of a substance is the weight of a given volume of that substance at 15.5° C. (59.9° F.) as compared with the weight of an equal volume of distilled water, at the same temperature unless otherwise specified." *Br.*

APPENDIX IX. Br.

Process of Percolation. Br.

"Moisten the solid materials with the prescribed quantity of menstruum, set aside for four hours in a well-closed vessel, pack in a percolator and add sufficient of the menstruum to saturate the materials and leave a layer of liquid above. Macerate for twenty-four hours; then allow percolation to proceed slowly until the percolate measures about three-fourths of the volume required for the finished tincture. Press the marc, mix the expressed liquid with the percolate, and add sufficient of the menstruum to produce the required volume. Clarify by subsidence or filtration, if necessary." *Br.*

Process of Repercolation. Br.

"Take one hundred parts by weight of the drug and divide it into five equal portions. Moisten the first portion with the menstruum, set aside in a closed vessel for four hours and pack in a percolator. Add sufficient of the menstruum to saturate the drug and leave a layer of liquid above. Macerate for twenty-four hours, then allow percolation to proceed slowly, collecting the percolate in fractions of twenty parts.

"Moisten the second portion of the drug with the first fraction of the percolate collected. Set aside, pack in a percolator, macerate and percolate as before, using as menstruum the successive fractions of percolate collected from the portion first treated. Again collect the percolate in fractions of twenty parts.

"In turn, treat in the manner described above the third, fourth, and fifth portions of the drug with the fractions of percolate obtained in the percolation of the portion immediately preceding, using the successive fractions of percolate in order, until a liquid extract is obtained of the required strength." *Br.*

Process of Maceration. Br.

"Place the solid materials with the whole of the menstruum in a closed vessel; shake occasionally during seven days; strain; press the marc; mix the liquids obtained. Clarify by subsidence or filtration if necessary." *Br.*

APPENDIX X. Br.

Process for Preparation of Discs (Lamellæ). Br.

"Discs are prepared by the following process:—Gelatin, 18 grammes; Glycerin, 2 grammes; Distilled Water, 88 grammes. Mix the Glycerin with the Distilled Water, allow the Gelatin to soak in the mixture till soft, and then dissolve by a gentle heat; cool the basis so produced. Take the prescribed quantity of the above basis, melt it by a gentle heat, add the prescribed quantity of medicament, dissolve and mix. Pour the melted and medicated basis upon a sheet of plate glass 10 centimetres square, previously thinly coated with White Beeswax, in such a manner that the solution is evenly distributed. Dry at a temperature not exceeding 36° C. (96.8° F.), and from the film thus obtained cut discs 3 millimetres nearly (⅛ inch) in diameter." *Br.*

APPENDIX XI. Br.

Processes for Preparation of Lozenges (Trochisci). Br.

With Fruit Basis.—"Take five hundred times the quantity of the drug ordered for one lozenge. Mix with it 6.5 grammes of Tragacanth and 26 grammes of Refined Sugar, both in fine powder. Add sufficient of the black-currant paste of commerce to produce 650 grammes, beat into a uniform mass, divide into 500 equal lozenges and dry in a hot air chamber at a moderate temperature." *Br.*

With Rose Basis.—"Take five hundred times the quantity of the drug ordered for one lozenge. Treat it as described under "Preparation with Simple Basis," previously mixing with the Refined Sugar 0.025 millilitre of oil of Rose." *Br.*

With Simple Basis.—"Take five hundred times the quantity of the drug ordered for one lozenge, mix it with 496 grammes of Refined Sugar and 19.5 grammes of Gum Acacia, both in fine powder. Make the mixture into a paste with 35 millilitres of Mucilage of Gum Acacia and a sufficient quantity of Distilled Water, divide into 500 equal lozenges and dry in a hot air chamber at a moderate temperature." *Br.*

With Tolu Basis.—"Take five hundred times the quantity of the drug ordered for one lozenge; dissolve such salts of alkaloids as may be ordered in 10 millilitres of Distilled Water; mix the solution with 482 grammes of Refined Sugar and 19.5 grammes of Gum Acacia, both in fine powder. Incorporate 10 millilitres of Tincture of Balsam of Tolu, and any other drugs ordered for the lozenges. Make into a paste with 35.5 millilitres of Mucilage of Gum Acacia and a sufficient quantity of Distilled Water; divide into 500 equal lozenges and dry in a hot-air chamber at a moderate temperature." *Br.*

APPENDIX XII. Br.

Alternative Preparations Sanctioned for Use in Tropical, Subtropical, and Other Parts of the British Empire. Br.

Aquæ Olei Anethi, Anisi, Carui, Cinnamomi, Fœniculi, Menthæ Piperitæ, Menthæ Viridis.—"Each of these Waters may be prepared by triturating the corresponding Oil with twice its weight of Calcium Phosphate and five hundred times its volume of Distilled Water and filtering the mixture. In tropical and subtropical parts of the Empire these Aquæ Olei may be used in place of the corresponding Aquæ of the Text of the Pharmacopœia." *Br.*

Emplastra.—"In tropical and subtropical parts of the Empire, more or less Hard Soap, Resin, or Yellow Beeswax, may be employed in the preparation of the Plasters of the Text of the Pharmacopœia, when prevailing high temperatures otherwise render the basis too soft for convenient use; but the official proportion of the active ingredient must in all cases be maintained." *Br.*

Extracta Liquida.—"Any Liquid Extract, defined in the Text of the Pharmacopœia, containing less than one-fourth of its weight of Alcohol (90 per cent.), may have the proportion of Alcohol (90 per cent.) increased to an amount not exceeding one-fourth of the weight of the Extract, in tropical and subtropical parts of the Empire where otherwise the preparation would be liable to ferment." *Br.*

Limonis Cortex Siccatus.—"In tropical and subtropical parts of the Empire, when fresh Lemon Peel cannot be obtained, Dried Lemon Peel may be used in preparing Compound Infusion of Orange Peel, Compound Infusion of Gentian, Syrup of Lemon, and Tincture of Lemon." *Br.*

Oleum Olivæ.—"In India, and in the Eastern, African, Australasian, and North American Divisions of the Empire, Arachis Oil or Sesame Oil, but no other oil or fat, may be employed in making the official Liniments, Plasters, Ointments, and Soaps for which Olive Oil is directed to be used." *Br.*

Suppositoria.—"More or less White Beeswax, according to prevailing temperatures, may be used in place of an equivalent amount of Oil of Theobroma in tropical and subtropical parts of the Empire, when otherwise the Suppositories of the Text of the Pharmacopœia would be too soft for convenient use." *Br.*

Syrupus Rhœados.—"In tropical and subtropical parts of the Empire, when prevailing high temperatures render this preparation liable to ferment, the proportion of Alcohol (90 per cent.) may be increased, but not to more than double the proportion stated in the Text of the Pharmacopœia, and equivalent quantity of Distilled Water being omitted." *Br.*

Unguenta.—"In tropical and subtropical parts of the Empire more or less Benzoated Lard, Prepared Lard, Benzoated Suet, Prepared Suet, Yellow Beeswax, or White Beeswax, may be employed in the preparation of the Ointments of the Text of the Pharmacopœia when prevailing high temperatures otherwise render the basis too soft for convenient use; but the official proportion of the active ingredient must in all cases be maintained." *Br.*

APPENDIX XIII. Br.

Table of Proportions Relating to the Preparation of Diluted Alcohols. Br.

"Volume of Alcohol (90 per cent.) to be diluted with Distilled Water to 1000 millilitres at 15.5° C. (59.9° F.) in order to give the Diluted Alcohols of the British Pharmacopœia." *Br.*

Alcohol Required.	Specific Gravity.	Volume of Alcohol (90 per cent.).
70 per cent.	0.8899	777.8 millilitres
60 per cent.	0.9134	666.7 millilitres
45 per cent.	0.9435	500.0 millilitres
20 per cent.	0.9760	222.2 millilitres

Elements and Pharmacopœial Chemicals (U. S. P. IX)

With Their Atomic or Molecular Weights and a Table of Multiples

This list contains the official chemicals and reagents of a definite composition, and also some that are not official, but which are likely to be required in stoichiometrical calculations. The figures in the list given below are based upon the Table of International Atomic Weights (1915), with Oxygen taken as 16. The elementary substances are also given in a separate list (see page 1760). In the case of a few salts, for which this Pharmacopœia has given no formula on account of the difficulty of securing an absolutely uniform composition, the theoretical formula has been inserted merely for information. In the case of many hydrated compounds the formula and molecular weight of the corresponding anhydrous salt have also been given, to save time in making calculations.

O-16

RELATIONS BETWEEN THERMOMETERS.

In *Fahrenheit's* thermometer, the freezing point of water is placed at 32°, and the boiling point at 212°, and the number of intervening degrees is 180.

The *Centigrade* or *Celsius's* thermometer, which is now recognized in the U. S. Pharmacopœia and has been adopted generally by scientists, marks the freezing point *zero*, and the boiling point 100°.

In *Réaumur's* thermometer the freezing point is at *zero*, and the boiling point at 80°.

In *De Lisle's* thermometer, used in Russia, the graduation begins at the boiling point, which is marked *zero*, while the freezing point is placed at 150°.

From the above statement, it is evident that 180 degrees of Fahrenheit are equal to 100° of the Centigrade, 80° of Réaumur, and 150° of De Lisle; or 1 degree of the first is equal to $\frac{5}{9}$ of a degree of the second, $\frac{4}{9}$ of a degree of the third, and $\frac{5}{6}$ of a degree of the last. It is easy, therefore, to convert the degrees of one into the equivalent number of degrees of the other; but in ascertaining the corresponding points upon the different scales, it is necessary to take into consideration their different modes of graduation. Thus, as the zero Fahrenheit is 32° below the point at which that of the Centigrade and of Réaumur is placed, this number must be taken into account in the calculation.

1. If any degree on the *Centigrade* scale, either above or below zero, be multiplied by 1.8 the result will, in either case, be the number of degrees above or below 32°, or the freezing point of *Fahrenheit*.

2. The number of degrees between any point of *Fahrenheit's* scale and 32°, if divided by 1.8, will give the corresponding point on the *Centigrade*.

Thermometric Equivalents

(U. S. P. IX)

Centigrade and Fahrenheit Scales

Given Centigrade:	Sought Fahrenheit:	Given Fahrenheit:	Sought Centigrade:
$n°\ \text{C.} = \frac{9n°}{5} + 32$		$n°\ \text{F.} = \frac{5(n° - 32)}{9}$

TABLES OF WEIGHTS AND MEASURES.

METRIC SYSTEM

The Metric System of Weights and Measures, which is the only one recognized by either the United States or British Pharmacopœias in their formulæ, is based on the idea of a correlation between the units of length, capacity and weight, and multiples and subdivisions of these units according to the decimal system. The unit of length is the *meter*. The cube of the tenth part of a meter is taken as the unit of capacity and is called a *liter*. The weight of one-thousandth part of a liter of distilled water at its maximum density is the unit of mass, and is denominated a *gramme*. The multiples of these measures, proceeding in the decimal progression, are distinguished by employing the prefixes *deca*,[1] *hecto*, *kilo*, and *myria*, taken from the Greek numerals, and the subdivisions, following the same order, by *deci*, *centi*, *milli*, from the Latin numerals. Since the introduction of this system it has been adopted by the principal nations of Europe, excepting Great Britain, and in many of these its use is compulsory. It is in general use in France, Germany, Austria-Hungary, Italy, Spain, Norway, Sweden, Netherlands, Switzerland, Greece, British India, and South America. It was legalized in Great Britain in 1864, and in the United States by an act of Congress in 1866.

The *meter*, or unit of length,	=	39.3700 inches.	
The *liter*, or unit of capacity,	=	33.813819776 fluidounces.	*U. S.*
The *gramme*, or unit of weight,	=	15.43235639 Troy grains.	

Upon this basis the following tables have been constructed:

Measures of Length.

		English Inches.		Miles.	Rods.	Yards.	Feet.	Inches.
Millimeter (mm.)	=	.03937						
Centimeter (cm.)	=	.39370						
Decimeter (dm.)	=	3.93700						
Meter (M.)	=	39.37000	=	0	0	1	0	3.370
Decameter (Dm.)	=	393.70000	=	0	0	10	2	9.700
Hectometer (Hm.)	=	3937.00000	=	0	0	109	1	1.000
Kilometer (Km.)	=	39370.00000	=	0	198	4	1	10.000
Myriameter (Mm.)	=	393700.00000	=	6	56	2	0	4.000

Measures of Capacity.

		English Cubic Inches.		Apothecaries' Measure.
Milliliter (mil)[2]	=	.0610233778	=	16.2306 minims.
Centiliter (cl.)	=	.6102337780	=	2.7051 fluidrachms.
Deciliter (dl.)	=	6.1023377800	=	3.3816 fluidounces.
Liter (L.)	=	61.0233778000	=	2.1133 pints.
Decaliter (Dl.)	=	610.2337780000	=	2.6417 gallons.
Hectoliter (Hl.)	=	6102.3377800000		
Kiloliter (Kl.)	=	61023.3778000000		
Myrialiter (Ml.)	=	610233.7780000000		

[1] Deca and hecto are sometimes written deka and hekto.

[2] Both the U. S. and British Pharmacopœias have adopted the more accurate and euphonious "mil" instead of the former "c.c.", as the word for the thousandth part of a liter.

Measures of Weight.

		Troy Grains.		℔ (Troy).	ʒ	ʔ	Gr.
Milligramme (mg.)	=	.0154					
Centigramme (cg.)	=	.1543					
Decigramme (dg.)	=	1.5432					
Gramme (Gm.)	=	15.4323		℔ (Troy).	ʒ	ʔ	Gr.
Decagramme (Dg.)	=	154.3235	=	0	0	2	34.3
Hectogramme (Hg.)	=	1543.2356	=	0	3	1	43.2
Kilogramme (Kg.)	=	15432.3563	=	2	8	1	12.3
Myriagramme (Mg.)	=	154323.5639	=	26	9	4	3.5

APOTHECARIES WEIGHTS.

In the United States the majority of physicians use in their prescriptions the so-called Apothecaries Weights, which are based on the old English Troy weights. It is to be noted that these weights, which are used in filling prescriptions, differ materially from the Avoirdupois weights, which are used in this work in the alternative formulæ for compounding the official preparations. In Great Britain the Avoirdupois system is used for prescribing, although physicians frequently insert, for convenience sake (there being no weight between the grain and the ounce), the Troy drachm of 60 grains.

The Apothecaries measure, as employed in the United States, differs from the Imperial measure used in Great Britain, in that the pint contains 16 fluidounces instead of 20; the British gallon being also correspondingly larger than the American.

APOTHECARIES WEIGHT.

Pound.		Troyounces.		Drachms.		Scruples.		Troy Grains
℔ 1	=	12	=	96	=	288	=	5760
		℥ 1	=	8	=	24	=	480
				ʒ 1	=	3	=	60
						℈ 1	=	gr. 20

The Imperial Standard Troy weight, at present recognized by the British laws, corresponds with the Apothecaries' weight in pounds, ounces, and grains; but differs from it in the division of the ounce, which, according to the former scale, contains twenty pennyweights, each weighing twenty-four grains.

AVOIRDUPOIS WEIGHT.

Pound.		Ounces.		Drachms.		Troy Grains.
℔ 1	=	16	=	256	=	7000
		oz. 1	=	16	=	437.5
				dr. 1		gr. 27.34375

Relative Value of Troy and Avoirdupois Weights.

Pound.		Pounds.	Pound.	Ounces.	Grains.
1 Troy	=	0.822857 Avoirdupois =	0	13	72.5
1 Avoirdupois	=	1.215277 Troy =	1	2	280

1 fluidounce	=			7	0	17.5	=		1	=	437.5	=	1.73296
1 fluidrachm	=				2	14.69	=				54.69	=	0.21662
1 minim	=										.91	=	0.00361

In converting the weights of liquids heavier or lighter than water into measures, or conversely, a correction must be made for specific gravity. In converting weights into measures, the calculator may proceed as if the liquid were water, and the obtained measure will be to the true measure *inversely* as the specific gravity. In the converse operation, of turning measures into weights, the same assumption may be made, and the obtained weight will be to the true weight *directly* as the specific gravity.

[1] The weight of a fluidounce of water at 25° C. (77° F.) according to the Table of Weight and Volume Relations in the U. S. Pharmacopœia IX is 454.6 grains.

APPROXIMATE MEASUREMENT.

For the sake of convenience, in the absence of proper instruments, we often make use of means of measurement which, though not precise nor uniform, afford results sufficiently accurate for ordinary purposes. Of this kind are certain household implements, of a capacity approaching to uniformity, and corresponding to a certain extent with the regular standard measures. Custom has attached a fixed value to these implements, with which it is proper that the practitioner should be familiar, although their capacity, as they are now made, with the exception of the wineglass, generally somewhat exceeds that at which they were originally and still continue to be estimated. According to the U. S. P. IX:

A *tea-cup* is estimated to contain about four fluidounces, or 120 mils
A *wineglass* . . . . . two fluidounces, or 60 mils
A *tablespoon* (cochlear magnum) . . . half a fluidounce, or 15 mils
A *dessertspoon* (cochlear medium) . . two fluidrachms, or 8 mils
A *teaspoon* (cochlear parvum) . . . . a fluidrachm, or 4 mils

Small quantities of liquid medicines are often administered by *drops*, each of which is usually considered equivalent to a minim, or the sixtieth part of a fluidrachm. The drop of water and of aqueous fluids is, sometimes, about that size; but the same is by no means the case with all medicinal liquids, and the drop even of the same liquid varies much in bulk, according to the circumstances under which it is formed. This is, therefore, an uncertain mode of estimating the quantity of liquids, and should be superseded where minim measures can be had. Certain rules, however, influence the formation of drops, which will enable us to form some notion of their probable relative number, in the same amount of liquid when possessed of the requisite data. Thus, the heavier the liquid, the smaller, other things being equal, is the size of the drops, and the greater their number in a given measure. The drop of chloroform, for example, which is a very heavy liquid, is very small, much smaller than that of alcohol or ether. The greater or less viscidity and greater or less mobility of the liquid have much influence, the former in increasing, the latter in diminishing the size of the drops. The adhesiveness of liquids, which opposes their disposition to leave the surface from which they fall, requires a greater mass to overcome it, and consequently augments the size of the drop. The rapidity of the movement acts in a contrary direction, and the drop from a full bottle should be less than from one more or less emptied. The broader the surface from which they fall, the greater is their size. The drops from a thick-lipped bottle are larger than from one with thin lips.

The results stated in the table on page 1773 were obtained by Stephen L. Talbot. They may be relied on as accurate, and in most cases correspond with the results obtained by Durand and Procter (see *A. J. P.*, i, 169; 1865, p. 389; 1880, p. 337), but should be considered as indicating only the relative number of drops afforded by the several liquids mentioned under the specific conditions of the experiment; for, under other circumstances than those of Talbot's experiments, entirely different results might be obtained as relates to each liquid.

FRENCH MEASURES.

In reading French medical works, if unacquainted with their customary expressions of measure, we are often left in great uncertainty as to the precise quantity indicated by the names. The following table, translated from the French Codex, will obviate this difficulty. (See Metric Table, page 1745.)

	Grammes.
A coffeespoon (*cuillerée à café*, Fr., *teaspoon*) (Fr. Cod. 1908)	5
A dessertspoon (*cuillerée à dessert*, Fr., *dessertspoon*), 2 coffeespoons, or	10
A common spoon (*cuillerée*, Fr., *tablespoon*), 4 coffeespoons, or	15
A glass (*verre*, Fr.), 10 common spoons	150
A handful (*poignée*, Fr.) of barleyseed (Fr. Cod. 1866)	80
" " " flaxseed	50
" " " flaxseed-meal	150
" " " dried mallow leaves	40
" " " " chicory "	30
A pinch (*pincée*, Fr.) of chamomile flowers	2
" " " arnica "	1
" " " marshmallow "	2
" " " mallows "	1
" " " linden "	2
" " " fruits of anise	2
" " " " fennel	2
A hen's egg, newly laid, has the mean weight of	64
" the white alone	40
" the yellow alone	20
Blanched almonds have the mean weight, each, of	1

TABLES SHOWING SPECIFIC GRAVITY CORRESPONDING WITH DEGREES OF HYDROMETERS.

Baumé's hydrometer is still largely employed. In this instrument the specific gravity of distilled water is assumed as the zero of the descending scale in relation to fluids heavier than itself, and as ten on the ascending scale in relation to lighter fluids. In the following tables the specific gravity of liquids is given corresponding with the several degrees of this hydrometer. The first column of specific gravities is taken from the French Codex. The second column is based on the calculations of Huss. The third column was calculated by Henry Pemberton of Philadelphia, in 1851. The figures in this column correspond with the degrees of the hydrometers formerly prepared by W. H. Pile.

The following formulas, furnished by Pile, may prove useful by enabling any one to calculate the sp. gr. corresponding with the several degrees of Baumé's hydrometer, and, conversely, the degree of Baumé corresponding with the sp. gr.

1. *For Liquids lighter than Water.*—The following formulas give the sp. gr. as represented in the first column in the foregoing table; or, the specific gravity being known, give the corresponding degree of Baumé.

$$\frac{144}{B^\circ + 134} = \text{sp. gr.}; \text{ and } \frac{144}{\text{sp. gr.}} - 134 = B^\circ.$$

The following formulas apply to the third column of specific gravities.

$$\frac{140}{B^\circ + 130} = \text{sp. gr.}; \text{ and } \frac{140}{\text{sp. gr.}} - 130 = B^\circ.$$

2. *For Liquids heavier than Water.*—For the first column, $\frac{144}{144 - B^\circ} = \text{sp. gr.}$, and $144 - \frac{144}{\text{sp. gr.}} = B^\circ$; for the third, $\frac{145}{145 - B^\circ} = \text{sp. gr.}$, and $145 - \frac{145}{\text{sp. gr.}} = B^\circ$.

Gay-Lussac's centesimal alcoholmeter is applicable only to alcohol. The scale of this instrument is divided into 100 unequal degrees, the zero corresponding to pure water, and 100° to absolute alcohol; and every intermediate degree expresses the percentage of pure alcohol, by measure, contained in the liquors examined. Thus, when the instrument stands at 40° in any alcoholic liquid, it indicates that 100 measures of the liquid contain 40 of pure alcohol and 60 of water. But, as it was graduated for the temperature of 59° of Fahrenheit, the liquors to be tested should be brought to that temperature. *Tralles's centesimal alcoholmeter* is the one used by the U. S. Government in gauging the strength of spirit, and is generally employed in this country by distillers and wholesale dealers in the purchase and sale of alcoholic liquors. The scale of this instrument is, like Gay-Lussac's, divided into 100 unequal parts, each corresponding to the percentage by volume of pure alcohol contained in the liquors examined. As the sp. gr. of water is considered as unity at its temperature of greatest density, 39.8° F., and the degrees of this scale are calculated for 60° F., the zero, corresponding to the density of water, will represent a sp. gr. of .9991.

The table of Tralles on page 1752 gives the percentage of alcohol *by volume* corresponding with the specific gravity. Under the heading of Alcohol tables (see page 1757), a table of the percentage by weight corresponding with the sp. gr. is given. By means of these tables, in connection with the alcoholmeter, every problem that can arise in reference to the strength of spirituous liquors can be solved; and by the appended table, giving the value of Baumé's degrees in those of Tralles, the facility is still further extended.

Sikes's hydrometer is used in Great Britain in the collection of the excise revenue: it is a brass instrument having a spherical bulb, with a weight at the bottom to make it float upright; the stem is divided into twenty parts, and every other division numbered, from 0 to 10. A series of nine weights are furnished with the instrument, numbered from 10 to 90; these are to be added to the weight at the bottom to cause the hydrometer to sink, so that a reading may be had on the graduated scale; this reading added to the number on the weight employed, gives a figure which indicates the strength of the spirit by referring to a table which accompanies the instrument.

Jones's hydrometer is similar to Sikes's, but by many is regarded as an improvement on it.

ALCOHOLMETRICAL TABLE OF TRALLES.

* Barometer 760 mm. Air one-half saturated with moisture.

|| If temperature of observation is above 15.56° C. (60.4° F.), look for percentage correction in the following table.

† Correction subtractive if barometer is above, additive if below, 760 mm. If barometer readings are in inches reduce to millimeters by multiplying by 25.4.

‡ Corresponding with a difference in specific gravity of 0.0001.

§ The figures on this line across the page are for fractional percentages below 1.

NOTE.—The figures of these Alcoholometric Tables are based on tables issued by the U. S. Bureau of Standards.

ALCOHOL.

According to E. R. Squibb.

NOTE.—This table was prepared by E. R. Squibb and introduced into the U. S. Pharmacopœia 1890, it is inserted here because it contains data not found in the official alcohol table U. S. P. IX.

PART I.—From 0 to 10 per cent. of Absolute Alcohol.

Specific Gravity. (Pure water at 15⅝° C. = 60° F. taken as unity.)		Percentage.				Weight of one gallon, at 15⅝° C. = 60° F.						Weight of 40 gallons to the nearest half pound, at 15⅝° C. = 60° F.	Weight of one pint, at 15⅝° C. = 60° F.	
								Avoirdupois Weight.						
											To the nearest ounce.			
At 15⅝° C. = 60° F.	At 25° C. = 77° F.	By weight.	By volume.	Under proof. (Brit. Excise.)	Of proof spirit. (U. S. Revenue.)	In Grammes.	In Grains.	lbs.	ozs.	Grs.	lbs.	ozs.	lbs.	In Grammes.	In Grains.

Formula for deriving above correction: Subtract algebraically the apparent specific gravity from 1.000 and multiply the remainder by 0.0011773. It is additive for specific gravities below, subtractive for those above, 1.000.

NOTE: The correction for reducing true to apparent specific gravity is found by subtracting algebraically 1.000 from the true specific gravity and multiplying the remainder by the factor 0.0011765. It is subtractive for specific gravities below, additive for those above, 1.000.

Reduction of Apparent Weight in Air to Weight in Vacuum (U. S. P. IX)

Weighings Made with Brass Weights, Temperature 25° C.,* Air One-half Saturated with Moisture,† and Barometer 760 mm.‡

* *Temperature correction*, approximate, for temperatures between 15° and 35° C. For each degree (centigrade) 0.37 per cent. of figures in table; additive if below, subtractive if above, 25° C.

† *Humidity correction* varies with temperature; additive if below, subtractive if above, 50 per cent. of saturation. For complete dryness or for full saturation at 15° C., the correction is 0.33 per cent. of figures in the table; at 20° C., 0.44 per cent.; at 25° C., 0.58 per cent.; at 30° C., 0.77 per cent.; and at 35° C., 1.01 per cent.

‡ *Barometer Correction* (important at high altitudes).—For each millimeter 0.132 per cent. of figures in table; additive if above 760 mm., subtractive if below 760 mm.

NOTE: If weights used are of platinum add 0.085 milligramme to, and if of aluminum subtract 0.312 milligramme from, the figures in the table for each gramme.

Weights and Volume Relations.

Specific gravity true $\frac{25°\ C.}{25°\ C.}$	Specific volume.	Weight of 1 U. S. gallon in pounds avoirdupois in air.	Weight of 100 fluid-ounces in ounces avoirdupois.	Weight of 1 fluidounce in grains.	Volume in U. S. gallons of 100 pounds avoirdupois.	Volume in fluidounces of 100 ounces avoirdupois.	Volume in fluidounces of 1000 grains.

PART III

SECTION 11

NATIONAL FORMULARY IV

The National Formulary, 4th edition, is issued by the American Pharmaceutical Association and Part I is here printed in abstract, with the permission of the Council of the Association. Part II of the National Formulary, which provides standards for drugs and chemicals used in N. F. formulas, but not included in the U. S. P., will be found chiefly in Part II of this Dispensatory, although some of the articles, when official also in the British Pharmacopœia, have been considered in Part I of the Dispensatory under the British titles.

The National Formulary was made one of the legal standards for drugs and medicines, under the National Food and Drugs Act of 1906, and has also been recognized by most State laws. It is intended to serve as a guide to pharmacists and physicians for preparations which are not in the United States Pharmacopœia but which are in use in this country.

ACETUM AROMATICUM. N. F.

Aromatic Vinegar [Acet. Arom.]

It contains the volatile oils of lavender, rosemary, juniper, peppermint, cinnamon, lemon and clove, dissolved in alcohol, acetic acid and water, and is used as a stimulating inhalant.

ACETUM OPII. N. F. (U. S. P. VIII)

Vinegar of Opium [Acet. Opii]

The process for this differs from that of the U. S. VIII in that percolation, as well as maceration, is used to extract the opium.

It represents 10 per cent. of opium in diluted acetic acid, and is flavored with myristica. The uses are the same as those of tincture of opium, the *dose* being eight minims (0.5 mil).

AQUA PHENOLATA. N. F.

Phenolated Water [Aq. Phenol. Carbolic Acid Water. Phenoli Soluto, P. I.]

This is a 2 per cent. solution of phenol in distilled water and is used as a lotion, gargle, etc.

CAFFEINÆ SODIO-SALICYLAS. N. F.

Caffeine Sodio-Salicylate [Caff. Sod.-Sal.]

This powder contains equal parts of caffeine and sodium salicylate. It is used for the same purposes as the caffeine sodio-benzoate (see Part I). The *dose* is three grains (0.2 Gm.).

CATAPLASMA KAOLINI. N. F. (U. S. P. VIII)

Cataplasm of Kaolin [Catapl. Kaolin.]

This is a mixture of kaolin, glycerin, boric acid, thymol and antiseptic oils used as a poultice for its emollient and anti-phlogistic properties. The only important difference in this process from that of the U. S. P. VIII is the requirement that the glycerin be rendered anhydrous by heating to 100° C. before mixing with the other ingredients.

CERATUM CAMPHORÆ. N. F. (U. S. P. VIII)

Camphor Cerate [Cerat. Camph.]

This preparation replaces the Ceratum Camphoræ Compositum of the N. F. III, and is composed of 10 per cent. of camphor liniment in a cerate base. The formula is essentially the same as that of the U. S. VIII.

CERATUM PLUMBI SUBACETATIS. N. F. (U. S. P. VIII)

Cerate of Lead Subacetate [Cerat. Plumb. Subacet. Goulard's Cerate]

This well-known cerate contains 20 per cent. of Goulard's extract mixed with a cerate base containing a little camphor. The formula differs from that of the U. S. VIII in substituting white wax for the paraffine. It is used as an astringent and sedative dressing.

CERATUM RESINÆ COMPOSITUM. N. F. (U. S. P. VIII)

Compound Rosin Cerate [Cerat. Resin. Co. Deshler's Salve]

This popular cerate contains rosin, yellow wax, suet, turpentine, and linseed oil. It is used as a stimulating dressing.

CHARTA POTASSII NITRATIS. N. F.

Potassium Nitrate Paper [Chart. Pot. Nit.]

This is made by saturating unsized paper in a strong solution of potassium nitrate and drying. It is used in asthma by burning it and inhaling the smoke.

CHLORAL CAMPHORATUM. N. F.

Camphorated Chloral [Chloral Camph.]

A eutectic mixture of equal parts of hydrated chloral and camphor, used as a local anodyne and counter-irritant.

COLLODIUM IODI. N. F.

Iodine Collodion [Collod. Iodi. Collodium Iodatum, N. F. III]

A five per cent., by weight, solution of iodine in flexible collodion. Used externally as a discutient and antiseptic.

COLLODIUM IODOFORMI. N. F.

Iodoform Collodion [Collod. Iodof. Collodium Iodoformatum, N. F. III]

A five per cent., by weight, solution of iodoform in flexible collodion. Used locally as an antiseptic protective.

COLLODIUM SALICYLICUM COMPOSITUM. N. F.

Compound Salicylic Collodion [Collod. Sal. Co. Corn Collodion, Collodium Salicylatum Compositum, N. F. III]

It contains salicylic acid, extract of cannabis, and flexible collodion. Used in the removal of corns.

COLLODIUM STYPTICUM. N. F. (Replacing U. S. P. VIII)

Styptic Collodion [Collod. Stypt.]

This is a 20 per cent., by weight, solution of tannic acid in flexible collodion. The new N. F. process is an improvement over that of the U. S. P. VIII, which directed only Collodion, not flexible Collodion, and diluted that with 30 per cent. of an alcohol-ether mixture.

It is used as a styptic application to cuts and small wounds.

COLLODIUM TIGLII. N. F.

Croton Oil Collodion [Collod. Tiglii]

A 10 per cent., by weight, solution of croton oil in flexible collodion. Used locally as a counter-irritant and vesicant.

CONFECTIO ROSÆ. N. F. (U. S. P. VIII)

Confection of Rose [Confect. Ros.]

The formula for this preparation is the same as that of the U. S. VIII (see p. 378). It is used principally as a pill excipient or vehicle.

CONFECTIO SENNÆ. N. F. (U. S. P. VIII)

Confection of Senna [Confect. Senn.]

The directions for this confection are the same as those of the U. S. VIII (see p. 378). This is the old *Lenitive Electuary* of bygone days. It contains senna, cassia fistula, tamarind, prune and fig, with sugar and oil of coriander. It is an agreeable lenitive or laxative in a *dose* of sixty grains (4 Gm.).

CORDIALE RUBI FRUCTUS. N. F.

Blackberry Cordial [Cord. Rubi Fruct.]

It contains cinnamon, clove, nutmeg, syrup of blackberry fruit, and diluted alcohol, and is used as a remedy in *diarrhea.*

Dose, two fluidrachms (8 mils).

DECOCTUM SARSAPARILLÆ COMPOSITUM. N. F.

Compound Decoction of Sarsaparilla [Decoc. Sarsap. Co.]

This is the old *Zittmann's decoction* and contains sarsaparilla, 10 per cent., sassafras, guaiac and glycyrrhiza, each, 2 per cent., and mezereum, 1 per cent. It is an alterative in *doses* of four fluidrachms (120 mils).

ELIXIRIA.

Elixirs

The elixirs should be perfectly clear preparations when dispensed. Purified talc or purified siliceous earth is recommended as a filtering medium for clarifying turbid elixirs. They should be made from fresh volatile oils of the finest quality and after making must not be exposed to extremes of temperature, but should be kept in tightly-stoppered bottles at the ordinary room temperature.

ELIXIR AMMONII BROMIDI. N. F.

Elixir of Ammonium Bromide [Elix. Ammon. Brom.]

It is made with ammonium bromide and a diluted and sweetened aromatic elixir. It con-

tains 5 grains of ammonium bromide in 1 fluidrachm of finished elixir.

The *dose* is one fluidrachm (4 mils).

ELIXIR AMMONII VALERATIS. N. F.

Elixir of Ammonium Valerate [Elix. Ammon. Valer. Elixir Ammonii Valerianatis, N. F. III]

This preparation is made with ammonium valerate and chloroform dissolved in aromatic elixir, colored with cudbear and flavored with vanilla. It contains 2 grains of ammonium valerate in 1 fluidrachm of finished elixir.

The *dose* is one fluidrachm (4 mils).

ELIXIR AMYGDALÆ COMPOSITUM. N. F.

Compound Elixir of Almond [Elix. Amygdal. Co.]

This is a new flavoring elixir of very low alcoholic strength, containing oil of bitter almond, vanillin, and orange flower water as the essential ingredients.

ELIXIR ANISI. N. F.

Elixir of Anise [Elix. Anis.]

This is an elixir containing a very low proportion of alcohol. It contains anethol, oil of fennel, spirit of bitter almond, alcohol, syrup and water. Used as a vehicle, also as a carminative for infants.

The *dose* for an infant is fifteen minims (1 mil).

ELIXIR AROMATICUM RUBRUM. N. F.

Red Aromatic Elixir [Elix. Arom. Rub. Red Elixir]

This is the U. S. P. aromatic elixir colored red with cudbear.

ELIXIR AURANTII AMARI. N. F. (To Replace Elixir Curassao, N. F. III)

Elixir of Bitter Orange [Elix. Aurant. Amar.]

This is an improvement upon the former elixir Curaçao. It contains oil of bitter orange, tincture of bitter orange peel, and orange flower water as the flavoring constituents.

ELIXIR BISMUTHI. N. F.

Elixir of Bismuth [Elix. Bismuth.]

This elixir is made from glycerite of bismuth, glycerin, distilled water, and aromatic elixir, and each mil represents the equivalent of 0.016 Gm. of bismuth oxide in the form of a tartrate. This is used as an intestinal astringent, but does not possess the therapeutic virtues of the insoluble bismuth salts.

The *dose* is one fluidrachm (4 mils).

ELIXIR BUCHU. N. F.

Elixir of Buchu [Elix. Buchu]

It contains fluidextract of buchu, alcohol, and aromatic elixir. About 7½ grains of buchu are represented by 1 fluidrachm of finished elixir. It is used as a diuretic.

The *dose* is one fluidrachm (4 mils).

ELIXIR BUCHU COMPOSITUM. N. F.

Compound Elixir of Buchu [Elix. Buchu Co.]

Compound fluidextract of buchu is used instead of the simple fluidextract. About 15 minims of compound fluidextract of buchu are represented in 1 fluidrachm of finished elixir. It is used as a diuretic.

The *dose* is one fluidrachm (4 mils).

ELIXIR BUCHU ET POTASSII ACETATIS. N. F.

Elixir of Buchu and Potassium Acetate [Elix. Buchu et Pot. Acet.]

This elixir contains 5 grains of potassium acetate and the equivalent of 7½ grains of buchu in 1 fluidrachm of finished elixir. It is used as a diuretic.

The *dose* is one fluidrachm (4 mils).

ELIXIR CALCII BROMIDI. N. F.

Elixir of Calcium Bromide [Elix. Calc. Brom.]

This is a solution of calcium bromide in aromatic elixir slightly acidulated with hydrobromic acid. It contains 5 grains of calcium bromide in 1 fluidrachm of finished elixir.

The *dose* is one fluidrachm (4 mils).

ELIXIR CALCII ET SODII GLYCEROPHOSPHATUM. N. F.

Elixir of Calcium and Sodium Glycerophosphates [Elix. Calc. et Sod. Glycerophos. Elixir Glycerophosphatum, N. F. III]

This elixir contains ¾ grain of sodium glycerophosphate and ½ grain calcium glycerophosphate in each fluidrachm.

The *dose* is one fluidrachm (4 mils).

ELIXIR CALCII HYPOPHOSPHITIS. N. F.

Elixir of Calcium Hypophosphite [Elix. Calc. Hypophos.]

This contains 2 grains of calcium hypophosphite in 1 fluidrachm of finished elixir. It is

as useless as the other preparations of the hypophosphites.

The *dose* is two fluidrachms (8 mils).

ELIXIR CALCII LACTOPHOSPHATIS. N. F.

Elixir of Calcium Lactophosphate [Elix. Calc. Lactophos.]

This elixir contains 1 grain of calcium lactate or about 1½ grains of so-called calcium lactophosphate in 1 fluidrachm of finished elixir.

The *dose* is two fluidrachms (8 mils).

ELIXIR CARDAMOMI COMPOSITUM. N. F.

Compound Elixir of Cardamom [Elix. Card. Co.]

This is a new elixir of very low alcoholic strength and pleasantly flavored with cardamom. It is used as a vehicle and flavoring agent.

ELIXIR CASCARÆ SAGRADÆ. N. F. Elixir Rhamni Purshianæ, N. F. III

Elixir of Cascara Sagrada [Elix. Cascar. Sagr.]

This is simply a mixture of equal parts of the aromatic fluidextract of cascara sagrada and aromatic elixir. About 30 grains of cascara sagrada are represented in 1 fluidrachm of the finished elixir.

The *dose* is one fluidrachm (4 mils).

ELIXIR CASCARÆ SAGRADÆ COMPOSITUM. N. F. Elixir Rhamni Purshianæ Compositum, N. F. III

Compound Elixir of Cascara Sagrada [Elix. Cascar. Sagr. Co. Laxative Elixir]

It contains about 7½ grains of cascara to each fluidrachm in addition to small amounts of senna and juglans. It is used as a laxative.

The *dose* is one fluidrachm (4 mils).

ELIXIR CATHARTICUM COMPOSITUM. N. F.

Compound Cathartic Elixir [Elix. Cathart. Co.]

This elixir represents, in each fluidrachm, about 7½ grains of frangula together with small quantities of senna and rhubarb, and is flavored with peppermint and aromatic elixir.

The *dose* is from one to three fluidrachms (4–12 mils).

ELIXIR CINCHONÆ ALKALOIDORUM. N. F. Elixir Cinchonæ, N. F. III

Elixir of Cinchona Alkaloids [Elix. Cinchon. Alk. Elixir Calisaya, Alkaloidal]

This elixir is now made from the alkaloid instead of the bark direct, and is simply a solution of cinchona alkaloids in aromatic elixir colored with cudbear. It contains about 1 grain of quinine sulphate and ½ grain each of cinchonidine and cinchonine sulphates in 1 fluidounce of finished elixir. It is used as a bitter, especially in conjunction with more active drugs.

The *dose* is two fluidrachms (8 mils).

ELIXIR CINCHONÆ ALKALOIDORUM ET FERRI. N. F. Elixir Cinchonæ et Ferri, N. F. III

Elixir of Cinchona Alkaloids and Iron [Elix. Cinchon. et Ferr. Ferrated Elixir of Calisaya, Alkaloidal]

This elixir contains 2 grains of soluble ferric phosphate in 1 fluidrachm of finished elixir. It is used as a chalybeate tonic.

The *dose* is two fluidrachms (8 mils).

ELIXIR CINCHONÆ ALKALOIDORUM ET HYPOPHOSPHITUM. N. F. Elixir Cinchonæ et Hypophosphitum, N. F. III

Elixir of Cinchona Alkaloids and Hypophosphites [Elix. Cinchon. et Hypophos. Elixir of Calisaya, Alkaloidal, with Hypophosphites]

This elixir contains 1 grain each of calcium and sodium hypophosphites in 1 fluidrachm of finished elixir. It is used as a tonic and alterative.

The *dose* is two fluidrachms (8 mils).

ELIXIR CINCHONÆ ALKALOIDORUM, FERRI, BISMUTHI ET STRYCHNINÆ. N. F. Elixir Cinchonæ, Ferri, Bismuthi et Strychninæ, N. F. III

Elixir of Cinchona Alkaloids, Iron, Bismuth and Strychnine [Elix. Cinchon. Ferr. Bism. et Strych. Elixir of Calisaya, Alkaloidal, with Iron, Bismuth, and Strychnine]

This elixir contains 1-100th of a grain of strychnine sulphate, 1 grain of bismuth and sodium tartrate and 2 grains of soluble ferric phosphate in 1 fluidrachm of finished elixir.

The *dose* is one fluidrachm (4 mils).

ELIXIR CINCHONÆ ALKALOIDORUM, FERRI ET BISMUTHI. N. F. Elixir Cinchonæ, Ferri et Bismuthi, N. F. III

Elixir of Cinchona Alkaloids, Iron, and Bismuth [Elix. Cinchon. Ferr. et Bism. Elixir of Calisaya, Alkaloidal, with Iron and Bismuth]

This preparation contains 1 grain of bismuth and sodium tartrate, about 1¾ grains of soluble ferric phosphate, in 1 fluidrachm of finished elixir.

The *dose* is two fluidrachms (8 mils).

ELIXIR CINCHONÆ ALKALOIDORUM, FERRI ET CALCII LACTOPHOSPHATIS. N. F. Elixir Cinchonæ, Ferri et Calcii Lactophosphatis, N. F. III

Elixir of Cinchona Alkaloids, Iron and Calcium Lactophosphate [Elix. Cinchon. Ferr. et Calc. Lactophos. Elixir of Calisaya, Iron and Lactophosphate of Lime]

This preparation contains ½ grain of calcium lactate (equivalent to about ¾ grain of the so-called calcium lactophosphate) and about 1 grain of soluble ferric phosphate in each fluidrachm.

The *dose* is two fluidrachms (8 mils).

ELIXIR CINCHONÆ ALKALOIDORUM, FERRI ET PEPSINI. N. F. Elixir Cinchonæ, Ferri et Pepsini, N. F. III

Elixir of Cinchona Alkaloids, Iron and Pepsin [Elix. Cinchon. Ferr. et Pepsin. Elixir of Calisaya, Alkaloidal, with Iron and Pepsin]

This preparation contains 1 grain of pepsin and about 1½ grains of soluble ferric phosphate in 1 fluidrachm of finished elixir.

The *dose* is two fluidrachms (8 mils).

ELIXIR CINCHONÆ ALKALOIDORUM, FERRI ET STRYCHNINÆ. N. F. Elixir Cinchonæ, Ferri et Strychninæ, N. F. III

Elixir of Cinchona Alkaloids, Iron and Strychnine [Elix. Cinchon. Ferr. et Strych. Elixir of Calisaya, Alkaloidal, with Iron and Strychnine]

This elixir contains 1-100th of a grain of strychnine sulphate and 2 grains of soluble ferric phosphate in 1 fluidrachm of finished elixir, and is used as a bitter tonic.

The *dose* is one fluidrachm (4 mils).

ELIXIR CORYDALIS COMPOSITUM. N. F.

Compound Elixir of Corydalis [Elix. Coryd. Co.]

This elixir contains about 3 grains of potassium iodide in 1 fluidrachm of finished elixir, with small quantities of the fluidextracts of corydalis, stillingia, xanthoxylum and blue flag.

The *dose* is one fluidrachm (4 mils).

ELIXIR ERIODICTYI AROMATICUM. N. F.

Aromatic Elixir of Eriodictyon [Elix. Eriodict. Arom. Aromatic Elixir of Yerba Santa. Elixir Corrigens]

This elixir is made from fluidextract of eriodictyon, syrup and compound elixir of taraxacum. It is used chiefly as a vehicle for disguising the taste of quinine sulphate and other bitter substances.

The *dose* is one fluidrachm (4 mils).

ELIXIR FERRI HYPOPHOSPHITIS. N. F.

Elixir of Ferric Hypophosphite [Elixir. Ferr. Hypophos.]

This elixir contains 1 grain of iron hypophosphite in 1 fluidrachm of finished elixir. It is used as an alterative and chalybeate tonic.

The *dose* is one fluidrachm (4 mils).

ELIXIR FERRI LACTATIS. N. F.

Elixir of Iron Lactate [Elix. Ferr. Lact.]

This elixir contains 1 grain of lactate of iron and 3 grains of potassium citrate in 1 fluidrachm of finished elixir.

The *dose* is one fluidrachm (4 mils).

ELIXIR FERRI PHOSPHATIS. N. F.

Elixir of Ferric Phosphate [Elix. Ferr. Phos.]

This elixir contains 2 grains of soluble ferric phosphate in 1 fluidrachm of the finished elixir.

The *dose* is one fluidrachm (4 mils).

ELIXIR FERRI PYROPHOSPHATIS. N. F.

Elixir of Ferric Pyrophosphate [Elix. Ferr. Pyrophos. Elixir of Pyrophosphate of Iron]

This elixir contains 2 grains of soluble ferric pyrophosphate in 1 fluidrachm of finished elixir. It is used as a chalybeate tonic.

The *dose* is one fluidrachm (4 mils).

ELIXIR FERRI PYROPHOSPHATIS, QUININÆ ET STRYCHNINÆ. N. F.

Elixir of Ferric Pyrophosphate, Quinine and Strychnine [Elix. Ferr. Pyrophos. Quin. et Strych.]

This elixir differs from the formerly official elixir of iron, quinine and strychnine phosphates in containing soluble ferric pyrophosphate instead of phosphate, while the quinine in the official elixir is replaced by quinine sulphate. It contains 1-128th grain of strychnine, ½ grain of quinine sulphate, and 2 grains of soluble ferric pyrophosphate in 1 fluidrachm of finished elixir.

The *dose* is one fluidrachm (4 mils).

ELIXIR FERRI, QUININÆ ET STRYCHNINÆ. N. F.

Elixir of Iron, Quinine and Strychnine [Elix. Ferr. Quin. et Strych.]

This elixir contains about 1 grain of ferric chloride, ½ grain quinine hydrochloride, and 1-100th grain of strychnine sulphate in 1 fluidrachm of finished elixir. It is used as a chalybeate tonic.

The *dose* is one fluidrachm (4 mils).

ELIXIR FORMATUM. N. F.

Elixir of Formates [Elix. Format.]

This is a new elixir which contains about 3 grains each of potassium and sodium formates in each fluidrachm. It is used as a diuretic but is of very doubtful service.

The *dose* is two fluidrachms (8 mils).

ELIXIR FORMATUM COMPOSITUM. N. F.

Compound Elixir of Formates [Elix. Format. Co.]

This is another new elixir containing the formates of lithium, sodium, magnesium, and strontium, with quinine. Its utility is very doubtful, to say the least.

The *dose* is two fluidrachms (8 mils).

ELIXIR GENTIANÆ. N. F.

Elixir of Gentian [Elix. Gent.]

It is made from fluidextract of gentian, compound, and is flavored with compound spirit of cardamom, but instead of being detannated by the ferric hydroxide process, compatibility with iron is achieved by the use of sodium citrate as an ingredient. It contains too small an amount of gentian to be therapeutically efficient. It is, however, often of service as a vehicle.

The *dose* is one fluidrachm (4 mils).

ELIXIR GENTIANÆ ET FERRI. N. F. Elixir Gentianæ cum Tinctura Ferri Chloridi, N. F. III

Elixir of Gentian and Iron [Elix. Gent. et Ferr. Elixir of Gentian with Tincture of Ferric Citro-Chloride]

Tincture of Citro-chloride of Iron, N. F., is used in this preparation along with the simple elixir of gentian. It represents ¾ of a grain of ferric chloride and nearly 2 grains of gentian in 1 fluidrachm. It is used as a bitter tonic.

The *dose* is one fluidrachm (4 mils).

ELIXIR GENTIANÆ ET FERRI PHOSPHATIS. N. F.

Elixir of Gentian and Ferric Phosphate [Elix. Gent. et Ferr. Phosph. Elixir Gentianæ Ferratum]

This elixir represents 1 grain of soluble ferric phosphate and about 2 grains of gentian in 1 fluidrachm of the finished elixir. It is used as a chalybeate and tonic.

The *dose* is one fluidrachm (4 mils).

ELIXIR GENTIANÆ GLYCERINATUM. N. F.

Glycerinated Elixir of Gentian [Elix. Gent. Glycerin.]

The formula for this tonic elixir has been materially changed as to flavor and sweetening. Saccharin is no longer used. It contains small amounts of gentian and taraxacum in a sweetened and flavored sherry wine. The last is its most active ingredient.

The *dose* is two fluidrachms (8 mils).

ELIXIR GLYCEROPHOSPHATUM COMPOSITUM. N. F.

Compound Elixir of Glycerophosphates [Elix. Glycerophos. Co. Compound Solution of Glycerophosphates]

This new elixir contains the glycerophosphates of sodium, calcium, iron, manganese, quinine, and strychnine. It represents about 2½ grains of combined glycerophosphates, 1/100 grain of strychnine and 1/6 grain of quinine in each fluidrachm.

The *dose* is two fluidrachms (8 mils).

ELIXIR GLYCYRRHIZÆ AQUOSUM. N. F.

Aqueous Elixir of Glycyrrhiza [Elix. Glycyrrh. Aq. Aqueous Elixir of Licorice]

This is a new non-alcoholic flavoring elixir containing fluidextract of licorice, compound spirit of cardamom, and orange flower water as the principal ingredients.

The *dose* is two fluidrachms (8 mils).

ELIXIR GLYCYRRHIZÆ AROMATICUM. N. F.

Aromatic Elixir of Glycyrrhiza [Elix. Glycyrrh. Arom. Aromatic Elixir of Licorice]

This elixir contains fluidextract of glycyrrhiza, oils of cloves, cinnamon, myristica and fennel, with aromatic elixir. It is used as a vehicle.

The *dose* is two fluidrachms (8 mils).

ELIXIR GUARANÆ. N. F.

Elixir of Guarana [Elix. Guar.]

This elixir is made from fluidextract of guarana, aromatic elixir and compound elixir of taraxacum. About 12 grains of guarana are represented in 1 fluidrachm of finished elixir.

The *dose* is one fluidrachm (4 mils).

ELIXIR HUMULI. N. F.

Elixir of Hops [Elix. Humul.]

This elixir is made from fluidextract of hops, tincture of vanilla, compound elixir of taraxa-

cum and aromatic elixir. About 7½ grains of hops are represented in 1 fluidrachm of finished elixir. It is used as a mild sedative.

The *dose* is two fluidrachms (8 mils).

ELIXIR HYPOPHOSPHITUM. N. F.

Elixir of Hypophosphites [Elix. Hypophos.]

This elixir contains 3 grains of calcium hypophosphite and 1 grain each of sodium and potassium hypophosphites in 1 fluidrachm of the finished preparation, and is used as an alterative.

The *dose* is two fluidrachms (8 mils).

ELIXIR HYPOPHOSPHITUM ET FERRI. N F. Elixir Hypophosphitum cum Ferro, N. F. III

Elixir of Hypophosphites and Iron [Elix. Hypophos. et Ferr.]

This elixir contains ½ grain each of potassium and ferrous hypophosphites and 1 grain each of calcium and sodium hypophosphites in 1 fluidrachm of finished elixir.

The *dose* is two fluidrachms (8 mils).

ELIXIR LITHII BROMIDI. N. F.

Elixir of Lithium Bromide [Elix. Lith. Brom.]

This elixir contains 5 grains of lithium bromide in 1 fluidrachm of finished preparation.

The *dose* is two fluidrachms (8 mils).

ELIXIR LITHII CITRATIS. N. F.

Elixir of Lithium Citrate [Elix. Lith. Cit.]

This elixir contains 5 grains of lithium citrate in 1 fluidrachm of finished preparation, and is used in the treatment of *gout* and *rheumatism,* but is more powerful for harm than good because of the alcohol and sugar it contains.

The *dose* is two fluidrachms (8 mils).

ELIXIR LITHII SALICYLATIS. N. F.

Elixir of Lithium Salicylate [Elix. Lith. Sal.]

This elixir contains 5 grains of lithium salicylate in 1 fluidrachm of finished preparation.

The *dose* is two fluidrachms (8 mils).

ELIXIR PEPSINI. N. F.

Elixir of Pepsin [Elix. Pepsin.]

This elixir is made from the glycerite of pepsin, hydrochloric acid and aromatic elixir. It represents about 1 grain of pepsin in 1 fluidrachm of finished preparation. It is very questionable whether the pepsin can retain its enzymic activity in the presence of so much alcohol as is in this elixir.

The *dose* is two fluidrachms (8 mils).

ELIXIR PEPSINI, BISMUTHI ET STRYCHNINÆ. N. F.

Elixir of Pepsin, Bismuth and Strychnine [Elix. Pepsin. Bism. et Strych.]

This elixir contains 1-100th of a grain of strychnine, ½ grain of pepsin and 2 grains of bismuth and sodium tartrate in 1 fluidrachm of finished preparation. It is an irrational combination.

The *dose* is one fluidrachm (4 mils).

ELIXIR PEPSINI ET BISMUTHI. N. F.

Elixir of Pepsin and Bismuth [Elix. Pepsin. et Bism.]

This elixir contains about ½ grain of pepsin and 2 grains of bismuth and sodium tartrate in 1 fluidrachm of finished preparation.

The *dose* is two fluidrachms (8 mils).

ELIXIR PEPSINI ET FERRI. N. F.

Elixir of Pepsin and Iron [Elix. Pepsin. et Ferr.]

This elixir is made from the tincture of ferric citro-chloride and elixir of pepsin. It contains 2 grains of ferric chloride and nearly 1 grain of pepsin in one fluidrachm of the finished preparation. It is believed by some that the pepsin renders the iron more acceptable to the stomach.

The *dose* is two fluidrachms (8 mils).

ELIXIR PEPSINI ET RENNINI COMPOSITUM. N. F. Essentia Pepsini, N. F. III

Compound Elixir of Pepsin and Rennin [Elix. Pepsin. et Rennin. Co.]

This elixir contains pepsin, rennin (an enzyme from calves' rennets), lactic acid, tincture of sweet orange peel, glycerin, alcohol, syrup, white wine and water. It is used as an aid to digestion.

The *dose* is two fluidrachms (8 mils).

ELIXIR PHOSPHORI. N. F.

Elixir of Phosphorus [Elix. Phosphor.]

This elixir contains one sixty-fourth of a grain of phosphorus in 1 fluidrachm of the finished preparation, and is flavored with compound spirit of orange and oil of anise. It affords an elegant and efficacious mode of exhibiting this remedy.

The *dose* is one fluidrachm (4 mils).

ELIXIR PHOSPHORI ET NUCIS VOMICÆ. N. F.

Elixir of Phosphorus and Nux Vomica [Elix. Phosphor. et Nuc. Vom.]

About 2 minims of tincture of nux vomica and about 1-64th of a grain of phosphorus are represented in 1 fluidrachm of the finished elixir.

The *dose* is one fluidrachm (4 mils).

ELIXIR POTASSII ACETATIS. N. F.

Elixir of Potassium Acetate [Elix. Pot. Acet.]

This elixir contains about 5 grains of potassium acetate in 1 fluidrachm of aromatic elixir. This proportion is so small that the preparation is therapeutically useless.

The *dose* is four fluidrachms (15 mils).

ELIXIR POTASSII ACETATIS ET JUNIPERI. N. F.

Elixir of Potassium Acetate and Juniper [Elix. Pot. Acet. et Junip.]

This elixir is made from potassium acetate, fluidextract of juniper, and aromatic elixir, and 5 grains of potassium acetate and 7½ grains of juniper are represented in 1 fluidrachm of the finished preparation. It is used as a diaphoretic.

The *dose* is four fluidrachms (15 mils).

ELIXIR POTASSII BROMIDI. N. F.

Elixir of Potassium Bromide [Elix. Pot. Brom.]

This elixir contains about 10 grains of potassium bromide in 1 fluidrachm of the finished preparation, and is used as a nerve sedative.

The *dose* is two fluidrachms (8 mils).

ELIXIR QUININÆ VALERATIS ET STRYCHNINÆ. N. F. Elixir Quininæ Valerianatis et Strychninæ, N. F. III

Elixir of Quinine Valerate and Strychnine [Elix. Quin. Valer. et Strych.]

This elixir is made from quinine valerate, strychnine sulphate, compound tincture of cudbear, and aromatic elixir, and contains 1 grain of quinine valerate and 1-100th of a grain of strychnine sulphate in 1 fluidrachm of finished preparation. It is used as a tonic and sedative in nervous affections.

The *dose* is one fluidrachm (4 mils).

ELIXIR RUBI COMPOSITUM. N. F.

Compound Elixir of Blackberry [Elix. Rubi Co.]

This elixir contains blackberry juice and blackberry root, galls, cinnamon, cloves, mace and ginger, with syrup, glycerin and diluted alcohol. It is used in the treatment of *diarrhea.*

The *dose* is four fluidrachms (15 mils).

ELIXIR SODII BROMIDI. N. F.

Elixir of Sodium Bromide [Elix. Sod. Brom.]

About 10 grains of sodium bromide are represented in 1 fluidrachm of finished elixir.

The *dose* is two fluidrachms (8 mils).

ELIXIR SODII HYPOPHOSPHITIS. N. F.

Elixir of Sodium Hypophosphite [Elix. Sod. Hypophos.]

Two grains of sodium hypophosphite are represented in 1 fluidrachm of the finished elixir.

The *dose* is one fluidrachm (4 mils).

ELIXIR SODII SALICYLATIS. N. F.

Elixir of Sodium Salicylate [Elix. Sod. Sal.]

Five grains of sodium salicylate are represented in 1 fluidrachm of the finished elixir. It is used in the treatment of *rheumatism.*

The *dose* is one fluidrachm (4 mils).

ELIXIR SODII SALICYLATIS COMPOSITUM. N. F.

Compound Elixir of Sodium Salicylate [Elix. Sod. Sal. Co.]

This new elixir contains in each fluidrachm about five grains of sodium salicylate, and one grain of potassium iodide with fluidextracts of gelsemium and cimicifuga. Such polypharmaceutical mixtures had better been left to extemporaneous prescription.

The *dose* is one fluidrachm (4 mils).

ELIXIR STRYCHNINÆ VALERATIS. N. F. Elixir Strychninæ Valerianatis, N. F. III

Elixir of Strychnine Valerate [Elix. Strych. Valer.]

It is made from strychnine valerate, acetic acid, tincture of vanilla, compound tincture of cudbear and aromatic elixir, and contains 1-100th grain of strychnine valerate in 1 fluidrachm of the finished elixir. It is used as a nervine.

The *dose* is one fluidrachm (4 mils).

ELIXIR TARAXACI COMPOSITUM. N. F.

Compound Elixir of Taraxacum [Elix. Tarax. Co.]

This elixir is made from fluidextracts of taraxacum, wild cherry and glycyrrhiza, with the tinctures of sweet orange peel and cinnamon, compound tincture of cardamom aromatic

elixir, and is used mainly as a vehicle to cover the taste of bitter substances.

The *dose* is two fluidrachms (8 mils).

ELIXIR TERPINI HYDRATIS. N. F.

Elixir of Terpin Hydrate [Elix. Terpin. Hyd.]

This elixir contains terpin hydrate, tincture of sweet orange peel, spirit of bitter almond, alcohol, glycerin, and syrup. About 1 grain of terpin hydrate is contained in 1 fluidrachm of the finished preparation.

The *dose* is one fluidrachm (4 mils).

ELIXIR TERPINI HYDRATIS ET CODEINÆ. N. F. Elixir Terpini Hydratis cum Codeina, N. F. III

Elixir of Terpin Hydrate and Codeine [Elix. Terpin. Hyd. et Codein.]

This elixir contains about 1 grain of terpin hydrate and about ⅛ grain of codeine in 1 fluidrachm of the finished preparation. It is a much misused mixture.

The *dose* is one fluidrachm (4 mils).

ELIXIR TERPINI HYDRATIS ET DIACETYLMORPHINÆ. N. F. Elixir Terpini Hydratis cum Heroina, N. F. III

Elixir of Terpin Hydrate and Diacetylmorphine [Elix. Terpin. Hyd. et Diacetylmorph.]

This elixir contains 1 grain of terpin hydrate and 1-64th of a grain of diacetylmorphine hydrochloride in 1 fluidrachm of the finished preparation.

The *dose* is one fluidrachm (4 mils).

ELIXIR TRIUM BROMIDORUM. N. F.

Elixir of Three Bromides [Elix. Tri. Brom.]

This is a new elixir containing in each fluidrachm five grains each of ammonium, potassium and sodium bromides, compound elixir of almond colored with cudbear, being used as the vehicle.

The *dose* is one fluidrachm (4 mils).

ELIXIR VANILLINI COMPOSITUM. N. F.

Compound Elixir of Vanillin [Elix. Vanil. Co.]

This new elixir, intended for a palatable vehicle, contains compound spirit of vanillin and is colored with tincture of caramel.

ELIXIR VIBURNI OPULI COMPOSITUM. N. F.

Compound Elixir of Viburnum Opulus [Elix. Viburn. Opul. Co.]

About 5 grains each of viburnum opulus and aletris and 10 grains of trillium with compound elixir of taraxacum are represented in 1 fluidrachm of the finished elixir. It is probably destitute of therapeutic virtues.

The *dose* is one fluidrachm (4 mils).

ELIXIR VIBURNI PRUNIFOLII. N. F.

Elixir of Viburnum Prunifolium [Elix. Viburn. Prun. Elixir of Black Haw]

This elixir is made from fluidextract of viburnum prunifolium, compound tincture of cardamom, and aromatic elixir, and contains about 7½ grains of viburnum prunifolium in 1 fluidrachm of the finished preparation.

The *dose* is one fluidrachm (4 mils).

ELIXIR ZINCI VALERATIS. N. F. Elixir Zinci Valerianatis, N. F. III

Elixir of Zinc Valerate [Elix. Zinc. Valer.]

This elixir is made from zinc valerate, citric acid, stronger ammonia water, alcohol, spirit of bitter almond, compound tincture of cudbear, and aromatic elixir. About 1 grain of zinc valerate is represented in 1 fluidrachm of the finished elixir. It is used as a nervine.

The *dose* is one fluidrachm (4 mils).

EMPLASTRUM FUSCUM CAMPHORATUM. N. F.

Camphorated Brown Plaster [Emp. Fusc. Camph. Camphorated Mother Plaster]

This plaster is made from red oxide of lead, olive oil, yellow wax and camphor, and is used as a protective in inflamed conditions of the skin or subcutaneous tissues.

EMPLASTRUM SAPONIS. N. F. (U. S. P. VIII)

Soap Plaster [Emp. Sapon.]

This is merely lead plaster with 10 per cent. of dried soap incorporated with it by the aid of a little water. The formula of the U. S. VIII is used, unchanged.

EMULSA. N. F.

Emulsions

In the National Formulary preference is given to acacia as the emulsifying agent, although other emulsifying agents are not ignored, as exemplified in the preparation of the numerous emulsions of cod liver oil. It is recommended that emulsions, being prone to deteriorate on standing, should be freshly prepared when needed. The following flavoring agents are suggested as being acceptable for cod-liver oil, the choice being left to the prescriber:

a. Oil of Betula ..... 4 mils
b. Oil of Betula ..... 2 mils
   Oil of Sassafras ..... 2 mils
c. Compound Spirit of Orange.... 1.5 mils
d. Oil of Betula ..... 2.00 mils
   Oil of Bitter Almond ..... 0.25 mil
   Oil of Coriander ..... 0.25 mil
e. Oil of Betula ..... 1.50 mils
   Oil of Sassafras ..... 1.50 mils
   Oil of Bitter Almond ..... 0.25 mil
f. Oil of Betula ..... 2.5 mils
   Oil of Bitter Almond ..... 2.5 mils

EMULSUM OLEI MORRHUÆ CUM CALCII LACTOPHOSPHATE. N. F.

Emulsion of Cod Liver Oil with Calcium Lactophosphate [Emul. Ol. Morrh. c. Calc. Lactophos.]

This emulsion contains 50 per cent. of cod liver oil, with calcium lactate, phosphoric acid, syrup of tolu and flavoring.

The *dose* is four fluidrachms (15 mils).

EMULSUM OLEI MORRHUÆ CUM CALCII PHOSPHATE. N. F.

Emulsion of Cod Liver Oil with Calcium Phosphate [Emul. Ol. Morrh. c. Calc. Phos. Emulsion of Cod Liver Oil with Phosphate of Lime]

This emulsion contains 50 per cent. of cod liver oil, with calcium phosphate, syrup of tolu and flavoring. It is used as an alterative.

The *dose* is four fluidrachms (15 mils).

EMULSUM OLEI MORRHUÆ CUM HYPOPHOSPHITIBUS. N. F. (U. S. P. VIII)

Emulsion of Cod Liver Oil with Hypophosphites [Emul. Ol. Morrh. c. Hypophos.]

This emulsion contains 50 per cent. of cod liver oil. Each dessertspoonful contains 1½ grains of calcium hypophosphite and ¾ grain each, of sodium and potassium hypophosphites with sufficient flavoring.

The *dose* is two fluidrachms (8 mils).

EMULSUM OLEI MORRHUÆ CUM MALTO. N. F.

Emulsion of Cod Liver Oil with Malt [Emul. Ol. Morrh. c. Malt.]

This emulsion contains 30 per cent. of cod liver oil with about 55 per cent. of extract of malt. It affords one of the most acceptable preparations of cod liver oil.

The *dose* is four fluidrachms (15 mils).

EMULSUM OLEI MORRHUÆ CUM PRUNO VIRGINIANA. N. F.

Emulsion of Cod Liver Oil with Wild Cherry [Emul. Ol. Morrh. c. Prun. Virg.]

This emulsion contains 50 per cent. of cod liver oil with fluidextract of wild cherry, syrup of tolu and flavoring. It is used as an alterative.

The *dose* is four fluidrachms (15 mils).

EMULSUM OLEI MORRHUÆ CUM VITELLO. N. F.

Emulsion of Cod Liver Oil with Egg [Emul. Ol. Morrh. c. Vitel.]

This emulsion contains 50 per cent. cod liver oil with glycerite of yolk of egg, syrup of tolu and flavoring. It is used as a tonic.

The *dose* is four fluidrachms (15 mils).

EMULSUM OLEI RICINI. N. F.

Emulsion of Castor Oil [Emul. Ol. Ricin.]

This emulsion contains 35 per cent. of castor oil, with tincture of vanilla, syrup and water. It is used as a cathartic.

The *dose* is one and one-half fluidounces (45 mils).

EMULSUM PETROLATI. N. F. Emulsum Petrolei, N. F. III

Emulsion of Petrolatum [Emul. Petrolat.]

This emulsion contains about 22.5 per cent. each, of white petrolatum, and expressed oil of almond, with acacia, tragacanth and syrup, tincture of lemon peel and water.

The *dose* is four fluidrachms (15 mils).

EXTRACTA. N. F.

Extracts

Pilular Extracts are stated to be solid or semi-solid products prepared by exhausting the powdered drugs with the proper solvents and carefully evaporating these solutions to the desired consistence. These extracts represent in a concentrated and relatively uniform condition, the useful constituents of the drug in a stable form suitable for medication. They are used extensively in pill masses, and are to be stored in tightly covered glass or porcelain jars.

Powdered Extracts are in dry, fine powders. They are often preferred to pilular extracts for general use, because they can be more accurately weighed, easily dispensed and can be preserved in tightly-stoppered bottles. (See also p. 440.)

For extracts that can be reliably assayed, alkaloidal standards have been adopted and assay methods are directed to determine their strength, and to provide for standardization.

EXTRACTUM ALOES. N. F. (U. S. P. VIII)

Extract of Aloes [Ext. Aloes. Powdered Extract of Aloes]

This extract differs from that of the U. S. VIII in that it is so made that one gramme

of the extract represents two grammes of aloes and also in its powder form. It is prepared by exhausting powdered aloes with boiling water, reducing the volume, by evaporation, to the proper consistence and using starch as the diluent.

The *dose* is two grains (0.125 Gm.).

EXTRACTUM CINCHONÆ. N. F.

Extract of Cinchona [Ext. Cinchon.]

Extract of cinchona yields not less than 22 per cent. nor more than 26 per cent. of the combined alkaloids of cinchona. It is prepared by exhausting the powdered cinchona with a menstruum of water and alcohol, evaporating the percolate to the proper consistence and after estimating the alkaloidal content, diluting to the standard strength with glucose. An assay is provided.

The *dose* is four grains (0.25 Gm.).

EXTRACTUM CONII. N. F.

Extract of Conium [Ext. Conii.]

Extract of conium yields not less than 1.8 per cent. nor more than 2.2 per cent. of coniine. This extract is prepared in the same manner as the preceding extract except that a small quantity of diluted hydrochloric acid is added previous to the evaporation of the percolate. An assay is provided.

The *dose* is one-half grain (0.03 Gm.).

EXTRACTUM ERGOTÆ AQUOSUM. N. F.

Aqueous Extract of Ergot [Ext. Ergot. Aq. Ergotin. Extractum Secalis Cornuti, P. I.]

This extract is prepared by percolating the powdered ergot, using chloroform water as menstruum, reducing to proper consistency by means of careful heat, and adding an equal weight of alcohol, and after allowing it to stand for three days, it is then filtered and the filtrate reduced to a pilular consistence. For reasons pointed out elsewhere (see *Ergota*, Part I) it does not fully represent the therapeutic virtues of ergot.

The *dose* is three grains (0.2 Gm.).

EXTRACTUM EUONYMI. N. F. (U. S. P. VIII)

Extract of Euonymus [Ext. Euonymi. Powdered Extract of Euonymus]

One gramme of the extract represents four grammes of euonymus. It is prepared by exhausting the powdered drug with 80 per cent. alcohol, evaporating to dryness, and diluting with starch. This process differs in several particulars from that formerly official.

CAUTION.—It has been stated that the absorption of euonymus in the gastro-intestinal tract is uncertain and irregular. To avoid an accumulation of the drug or toxic action, the physician should carefully guard the dosage and determine in each case the tolerance of the patient.

The *dose* is two grains (0.125 Gm.).

EXTRACTUM FERRI POMATUM. N. F.

Ferrated Extract of Apples [Ext. Ferr. Pomat. Ferri Malas Crudus. Crude Malate of Iron]

This extract is made from iron wire, ripe sour apples and water, and is used as a chalybeate.

The *dose* is ten grains (0.65 Gm.).

EXTRACTUM HÆMATOXYLI. N. F. (U. S. P. VIII)

Extract of Hematoxylon [Ext. Hæmatox.]

This extract is prepared by exhausting the rasped drug with boiling water and evaporating the extract to dryness precisely as in the U. S. VIII.

The *dose* is fifteen grains (1 Gm.).

EXTRACTUM IGNATIÆ. N. F.

Extract of Ignatia [Ext. Ignat. Powdered Extract of Ignatia]

Extract of ignatia yields not less than 5.4 per cent. nor more than 6.6 per cent. of the combined alkaloids of ignatia. It is prepared by exhausting the powdered drug with 75 per cent. alcohol, evaporating to dryness, weighing, and assaying at this stage, and finally diluting to the proper standard with starch.

The *dose* is one-half grain (0.03 Gm.).

EXTRACTUM JALAPÆ. N. F.

Extract of Jalap [Ext. Jalap.]

This pilular extract is prepared by exhausting the jalap with alcohol and evaporating to a pilular consistence.

The *dose* is fifteen grains (1 Gm.).

EXTRACTUM KRAMERIÆ. N. F. (U. S. P. VIII)

Extract of Krameria [Ext. Kramer. Powdered Extract of Krameria]

One gramme of the extract represents four grammes of krameria. It is prepared by exhausting the powdered drug with cold water. The percolate is then heated to boiling, strained, and the strained liquid evaporated to dryness and sufficient dried starch added as diluent.

The *dose* is eight grains (0.5 Gm.).

EXTRACTUM LEPTANDRÆ. N. F. (U. S. P. VIII)

Extract of Leptandra [Ext. Leptand. Powdered Extract of Leptandra]

One gramme of the extract represents four grammes of leptandra. It is prepared by exhausting the drug with a menstruum of 75 per cent. alcohol, evaporating the percolate to dryness and diluting with dried starch.

The *dose* is four grains (0.25 Gm.).

EXTRACTUM PODOPHYLLI. N. F.

Extract of Podophyllum [Ext. Podophyl.]

This extract is prepared by exhausting the powdered drug with 80 per cent. alcohol and evaporating to a pilular consistence.

The *dose* is one-fourth grain (0.015 Gm.).

EXTRACTUM QUASSIÆ. N. F. (U. S. P. VIII)

Extract of Quassia [Ext. Quas. Powdered Extract of Quassia]

One gramme of the extract represents ten grammes of quassia. Water is used as a menstruum in the preparation of this extract. The aqueous percolate is reduced to three-fourths of its bulk by boiling, strained, and then evaporated to dryness, powdered, and diluted to the proper weight with dried starch.

The *dose* is one grain (0.06 Gm.).

FERRI OXIDUM SACCHARATUM. N. F.

Saccharated Ferric Oxide [Ferr. Oxid. Sacch. Soluble Ferric Oxide. Ferrum Oxydatum Saccharatum. Eisenzucker]

Saccharated ferric oxide contains the equivalent of not less than 2.8 per cent. of Fe. In the preparation of this product, freshly precipitated ferric hydroxide is dissolved in a heavy sugar syrup by the addition of a small quantity of sodium hydrate. This solution is then evaporated on a water bath and enough sugar added to bring it to the desired weight. An assay process is given.

FLUIDEXTRACTA. N. F.

Fluidextracts

Fluidextracts are strong liquid preparations of vegetable drugs, containing alcohol either as a solvent or as a preservative, and prepared so that one mil of the fluidextract approximately represents the activity of one gramme of the air-dried and powdered drug of standard quality. Fluidextracts should be stored in amber-colored bottles protected from sunlight and extremes of temperature. (See also *Fluidextracta,* Part I.)

FLUIDEXTRACTUM ADONIDIS. N. F.

Fluidextract of Adonis [Fldext. Adonid.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum. It is used as a heart stimulant.

The *dose* is two minims (0.125 mil).

FLUIDEXTRACTUM ALETRIDIS. N. F.

Fluidextract of Aletris [Fldext. Aletrid.]

Prepared by using diluted alcohol as the menstruum. It is used as an alterative.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM ANGELICÆ RADICIS. N. F.

Fluidextract of Angelica Root [Fldext. Angel. Rad.]

Prepared by using alcohol as the menstruum. It is used as a stimulant and carminative.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM APII FRUCTUS. N. F. Fluidextractum Apii Graveolens, N. F. III

Fluidextract of Celery Fruit [Fldext. Apii Fruct.]

Prepared by using alcohol as the menstruum. In order to remove any separated oil, after permitting the fluidextract to stand, filter it through an alcohol-wetted filter, rejecting the final few millilitres remaining on the filter with the oil.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM APOCYNI. N. F. (U. S. P. VIII)

Fluidextract of Apocynum [Fldext. Apocyn.]

Prepared by using one volume of glycerin, six volumes of alcohol and three volumes of water as menstruum I, and three volumes of alcohol and two volumes of water as menstruum II. The increase in the proportion of alcohol, over that of the U. S. VIII, is an advantage.

CAUTION.—It has been stated that the absorption of apocynum in the gastro-intestinal tract is uncertain and irregular. To avoid an accumulation of the drug or toxic action, the physician should carefully guard the dosage and determine in each case the tolerance of the patient.

The *dose* is twelve minims (0.75 mil).

FLUIDEXTRACTUM ARALIÆ. N. F. Fluidextractum Araliæ Racemosa, N. F. III

Fluidextract of Aralia [Fldext. Aral.]

Prepared by using two volumes of alcohol and one voulme of water as the menstruum. It is used as an alterative.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM ARNICÆ. N. F. Fluidextractum Arnicæ Florum, N. F. III

Fluidextract of Arnica [Fldext. Arnic.]

Prepared by using diluted alcohol as the menstruum. It is used as a stimulant and alterative.

The *dose* is one and one-half minims (0.1 mil).

FLUIDEXTRACTUM ASCLEPIADIS. N. F.

Fluidextract of Asclepias [Fldext. Asclepiad.]

Prepared by using diluted alcohol as the menstruum. It is used as a diaphoretic, emetic, and cathartic.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM BAPTISIÆ. N. F.

Fluidextract of Baptisia [Fldext. Baptis.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum. It is used as a laxative and stimulant, in large doses being emetic and cathartic.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM BERBERIDIS. N. F. (U. S. P. VIII)

Fluidextract of Berberis [Fldext. Berberid.]

Prepared by using diluted alcohol as the menstruum. It is used as an astringent tonic and cathartic.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM BOLDI. N. F.

Fluidextract of Boldo [Fldext. Boldi]

Prepared by using alcohol as the menstruum. It is used as an alterative and tonic.

The *dose* is eight minims (0.5 mil).

FLUIDEXTRACTUM BUCHU COMPOSITUM. N. F.

Compound Fluidextract of Buchu [Fldext. Buchu Co.]

Prepared by using two volumes of alcohol and one volume of water as the menstruum. Each fluidrachm represents 37½ grains of buchu and 7½ grains each of cubeb, juniper and uva ursi.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM CALENDULÆ. N. F.

Fluidextract of Calendula [Fldext. Calend.]

Prepared by using alcohol as the menstruum. It is used as a stimulant embrocation in sprains and bruises.

FLUIDEXTRACTUM CALUMBÆ. N. F. (U. S. P. VIII)

Fluidextract of Calumba [Fldext. Calumb.]

Prepared by using one volume of glycerin, eight volumes of alcohol, and one volume of water as menstruum I, and four volumes of alcohol and one volume of water as menstruum II. It is used as a stomachic.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM CASTANEÆ. N. F.

Fluidextract of Chestnut Leaves [Fldext. Castan.]

Prepared by using boiling water as the menstruum and adding ten volumes of glycerin and twenty volumes of alcohol being added as a preservative. It is used as an astringent.

The *dose* is one fluidrachm (4 mils).

FLUIDEXTRACTUM CATARIÆ. N. F.

Fluidextract of Catnep [Fldext. Catar.]

Prepared by using three volumes of alcohol and four volumes of water as the menstruum. It is used as a carminative, antispasmodic and emmenagogue.

The *dose* is one fluidrachm (4 mils).

FLUIDEXTRACTUM CAULOPHYLLI. N. F.

Fluidextract of Caulophyllum [Fldext. Caulophyl.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum. It is used as a diuretic and emmenagogue.

The *dose* is eight minims (0.5 mil).

FLUIDEXTRACTUM CHIMAPHILÆ. N. F. (U. S. P. VIII)

Fluidextract of Chimaphila [Fldext. Chimaphil.]

Prepared by using diluted alcohol as the menstruum. It is used chiefly for its effects on the mucous membrane of the bladder and urethra.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM CHIONANTHI. N. F.

Fluidextract of Chionanthus [Fldext. Chionanth.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum. It is used as a diuretic.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM CHIRATÆ. N. F. (U. S. P. VIII)

Fluidextract of Chirata [Fldext. Chirat.]

Prepared by using diluted alcohol as the menstruum. It is used as a tonic and febrifuge.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM CINCHONÆ AQUOSUM. N. F.

Aqueous Fluidextract of Cinchona [Fldext. Cinchon. Aq.]

One hundred millilitres of aqueous fluidextract of cinchona yields not less than 4.5 Gm. nor more than 5.5 Gm. of the alkaloids of cinchona, and not less than 12 per cent. of alcohol, by volume. Prepared by using a menstruum of 125 mils of glycerin and 30 mils of hydrochloric acid in water. The percolate thus obtained is assayed and enough alcohol and water added so that it conforms to the stipulated standards. An assay is provided in the text. It is used as a bitter tonic.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM COCILLANÆ. N. F.

Fluidextract of Cocillana [Fldext. Cocillan.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum. It is used as an expectorant, emetic, and laxative.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM COFFEÆ. N. F. Fluidextractum Coffeæ Tostæ, N. F. III

Fluidextract of Coffee [Fldext. Coff.]

Prepared by using 65 mils of glycerin, 250 mils of alcohol, and 685 mils of water as menstruum I, and one volume of alcohol and three volumes of water as menstruum II.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM COLCHICI CORMI. N. F. Fluidextractum Colchici Radicis, N. F. III

Fluidextract of Colchicum Corm [Fldext. Colch. Corm.]

One hundred millilitres of fluidextract of colchicum corm yields not less than 0.31 Gm. nor more than 0.39 Gm. of colchicine. Prepared by using a menstruum of two volumes of alcohol and one volume of water. After assaying adjust the volume of the finished product to conform with the required standard. An assay is provided in the text.

The *dose* is three minims (0.2 mil).

FLUIDEXTRACTUM CONDURANGO. N. F.

Fluidextract of Condurango [Fldext. Condurango]

Prepared by using diluted alcohol as the menstruum. It is used as an alterative and stomachic.

The *dose* is one fluidrachm (4 mils).

FLUIDEXTRACTUM CONII. N. F. (U. S. P. VIII)

Fluidextract of Conium [Fldext. Conii]

One hundred millilitres of fluidextract of conium yields not less than 0.35 Gm. nor more than 0.45 Gm. of coniine. Prepared by using a menstruum of twenty mils of acetic acid and nine hundred and eighty mils of diluted alcohol. This is assayed and enough of a similar menstruum added to bring the fluidextract to the required standard. An assay is provided in the text.

The *dose* is three minims (0.2 mil).

FLUIDEXTRACTUM CONVALLARIÆ FLORUM. N. F. Fluidextractum Convallariæ, N. F. III

Fluidextract of Convallaria Flowers [Fldext. Conval. Flor.]

Prepared by using two volumes of alcohol and one volume of water as the menstruum. It is used as a cardiac stimulant and diuretic.

The *dose* is eight minims (0.5 mil).

FLUIDEXTRACTUM CONVALLARIÆ RADICIS. N. F. (U. S. P. VIII)

Fluidextract of Convallaria Root [Fldext. Conval. Rad.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum. It is used as a diuretic and heart tonic.

The *dose* is eight minims (0.5 mil).

FLUIDEXTRACTUM COPTIS. N. F.

Fluidextract of Coptis [Fldext. Copt.]

Prepared by using diluted alcohol as the menstruum. It is used as a tonic and stimulant.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM CORNI. N. F. Fluidextractum Cornus, N. F. III

Fluidextract of Cornus [Fldext. Corni]

Prepared by using 150 mils of glycerin and 850 mils of diluted alcohol as menstruum I, and diluted alcohol as menstruum II. It is used as a tonic.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM CORYDALIS. N. F.

Fluidextract of Corydalis [Fldext. Corydal.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum. It is used as an alterative and diuretic.

The *dose* is ten minims (0.65 mil).

FLUIDEXTRACTUM CUBEBÆ. N. F. (U. S. P. VIII)

Fluidextract of Cubeb [Fldext. Cubeb.]

Prepared by using alcohol as the menstruum. It is used as a diuretic and expectorant.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM CYPRIPEDII N. F. (U. S. P. VIII)

Fluidextract of Cypripedium [Fldext. Cypriped.]

Prepared by using diluted alcohol as the menstruum. It is used as a nerve stimulant, antispasmodic, and analgesic.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM DAMIANÆ. N. F. Fluidextractum Turneræ, N. F. III

Fluidextract of Damiana [Fldext. Damian.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum. It is attributed, but probably erroneously so, with aphrodisiac powers.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM DIOSCOREÆ. N. F.

Fluidextract of Dioscorea [Fldext. Dioscor.]

Prepared by using four volumes of alcohol and one volume of water as the menstruum. It is used as an expectorant and diaphoretic.

The *dose* is one fluidrachm (4 mils).

FLUIDEXTRACTUM DROSERÆ. N. F.

Fluidextract of Drosera [Fldext. Droser.]

Prepared by using two volumes of alcohol and one volume of water as the menstruum. It is used as an antispasmodic.

The *dose* is one fluidrachm (4 mils).

FLUIDEXTRACTUM DULCAMARÆ. N. F.

Fluidextract of Bittersweet [Fldext. Dulcam.]

Prepared by using diluted alcohol as the menstruum. It is used as a diuretic and alterative.

The *dose* is one fluidrachm (4 mils).

FLUIDEXTRACTUM ECHINACEÆ. N. F.

Fluidextract of Echinacea [Fldext. Echin.]

Prepared by using four volumes of alcohol and one volume of water as the menstruum. It is used as an alterative.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM EUONYMI. N. F. (U. S. P. VIII)

Fluidextract of Euonymus [Fldext. Euonym.]

Prepared by using four volumes of alcohol and one volume of water as the menstruum. It is used as a laxative and as a diuretic.

The *dose* is eight minims (0.5 mil).

CAUTION.—It has been stated that the absorption of euonymus in the gastro-intestinal tract is uncertain and irregular. To avoid an accumulation of the drug or toxic action, the physician should carefully guard the dosage and determine in each case the tolerance of the patient.

FLUIDEXTRACTUM EUPATORII. N. F. (U. S. P. VIII)

Fluidextract of Eupatorium [Fldext. Eupator.]

Prepared by using diluted alcohol as a menstruum. It is used as an alterative, diaphoretic and tonic.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM EUPHORBIÆ PILULIFERÆ. N. F.

Fluidextract of Euphorbia Pilulifera [Fldext. Euphorb. Pilul.]

Prepared by using diluted alcohol as the menstruum. It is used as an expectorant and emetic.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM FUCI. N. F.

Fluidextract of Fucus [Fldext. Fuci]

Prepared by using three volumes of alcohol and one volume of water as the menstruum. It is used as a remedy for *obesity*.

The *dose* is ten minims (0.65 mil).

FLUIDEXTRACTUM GALEGÆ. N. F.

Fluidextract of Galega [Fldext. Galeg.]

Prepared by using diluted alcohol as the menstruum. It is used as a galactagogue and diuretic.

The *dose* is one fluidrachm (4 mils).

FLUIDEXTRACTUM GERANII. N. F. (U. S. P. VIII)

Fluidextract of Geranium [Fldext. Geran.]

Prepared by using one volume of glycerin, six volumes of alcohol and one volume of water as menstruum I, and three volumes of alcohol and two volumes of water as menstruum II. It is used as an astringent and styptic.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM GOSSYPII CORTICIS.

N. F. Fluidextractum Gossypii Radicis, N. F. III

Fluidextract of Cotton Root Bark [Fldext. Gossyp. Cort.]

Prepared by using alcohol as the menstruum. It is used as an oxytoccic and emmenagogue.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM HAMAMELIDIS FOLIORUM. N. F. (U. S. P. VIII)

Fluidextract of Hamamelis Leaves [Fldext. Hamamel. Fol.]

Prepared by using one volume of glycerin, three volumes of alcohol, and five volumes of water as menstruum I, and one volume of alcohol and two volumes of water as menstruum II. It is used as an astringent.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM HELIANTHEMI. N. F.

Fluidextract of Helianthemum [Fldext. Helianth.]

Prepared by using diluted alcohol as the menstruum. It is used as an alterative and astringent.

The *dose* is one fluidrachm (4 mils).

FLUIDEXTRACTUM HELONIADIS. N. F.

Fluidextract of Helonias [Fldext. Helon.]

Prepared by using diluted alcohol as the menstruum. It is used as a tonic, diuretic, and anthelmintic.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM HUMULI. N. F.

Fluidextract of Hops [Fldext. Humul.]

Prepared by using five volumes of alcohol and three volumes of water as the menstruum. It is used as a nerve sedative.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM HYDRANGEÆ. N. F.

Fluidextract of Hydrangea [Fldext. Hydrang.]

Prepared by using three volumes of alcohol and two volumes of water as the menstruum. It is used as a diuretic.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM IRIDIS VERSICOLORIS. N. F.

Fluidextract of Blue Flag [Fldext. Iris Vers. Fluidextractum Iridis, N. F. III]

Prepared by using alcohol as the menstruum. It is used as an alterative and cholagogue cathartic.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM JALAPÆ. N. F.

Fluidextract of Jalap [Fldext. Jalap.]

Prepared by mixing the drug with clean sand and using alcohol as the menstruum. It is used as a cathartic.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM JUGLANDIS. N. F.

Fluidextract of Juglans [Fldext. Jugland.]

Prepared by using 100 mils of glycerin, 500 mils of alcohol and 400 mils of water as menstruum I, and diluted alcohol as menstruum II. It is used as a cathartic.

The *dose* is one fluidrachm (4 mils).

FLUIDEXTRACTUM JUNIPERI. N. F.

Fluidextract of Juniper Berries [Fldext. Junip.]

Prepared by using diluted alcohol as the menstruum. It is used as a diuretic.

The *dose* is one fluidrachm (4 mils).

FLUIDEXTRACTUM KAVÆ. N. F.

Fluidextract of Kava [Fldext. Kav.]

Prepared by using three volumes of alcohol and two volumes of water as the menstruum. It is used as a diuretic and alterative.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM KOLÆ. N. F.

Fluidextract of Kola [Fldext. Kol. Fluidextractum Sterculiæ, N. F. III]

Prepared by using two volumes of alcohol and one volume of water as the menstruum. It is used for the same purposes as caffeine.

The *dose* is one fluidrachm (4 mils).

FLUIDEXTRACTUM KRAMERIÆ. N. F. (U. S. P. VIII)

Fluidextract of Krameria [Fldext. Kramer.]

Prepared by using one volume of glycerin, five volumes of alcohol and four volumes of water as menstruum I, and diluted alcohol as menstruum II. The menstruum of the U. S. P. VIII was diluted alcohol. It is used as an astringent.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM LAPPÆ. N. F. (U. S. P. VIII)

Fluidextract of Lappa [Fldext. Lapp.]

Prepared by using diluted alcohol as the menstruum; no change from the U. S. P. VIII. It is used as an alterative and diaphoretic.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM LEPTANDRÆ. N. F. (U. S. P. VIII)

Fluidextract of Leptandra [Fldext. Leptand.]

Prepared by using diluted alcohol as the menstruum—the U. S. P. VIII directed the use of three volumes of alcohol and one volume of water as the menstruum. It is used as a laxative.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM LUPULINI. N. F. (U. S. P. VIII)

Fluidextract of Lupulin [Fldext. Lupulin.]

It is made with alcohol, as directed by the U. S. P. VIII, and each mil of fluidextract represents 1 Gm. of drug. It is used as a nerve sedative.

The *dose* is eight minims (0.5 mil).

FLUIDEXTRACTUM MATICO. N. F. (U. S. P. VIII)

Fluidextract of Matico [Fldext. Matic.]

Prepared by using three volumes of alcohol and one volume of water, as directed by the U. S. P. VIII, as the menstruum. It is used as an intestinal astringent and diuretic.

The *dose* is one fluidrachm (4 mils).

FLUIDEXTRACTUM MEZEREI. N. F. (U. S. P. VIII)

Fluidextract of Mezereum [Fldext. Mezer.]

Prepared by using four volumes of alcohol and one volume of water as the menstruum. It is used as an alterative and rubefacient.

FLUIDEXTRACTUM PARACOTO. N. F.

Fluidextractum Coto, N. F. III
Fluidextract of Paracoto [Fldext. Paracot.]

Prepared by using nine volumes of alcohol and one volume of water as the menstruum. It is used as an intestinal astringent.

The *dose* is five minims (0.3 mil).

FLUIDEXTRACTUM PAREIRÆ. N. F. (U. S. P. VIII)

Fluidextract of Pareira [Fldext. Pareir.]

Prepared by using diluted alcohol as the menstruum—the U. S. P. VIII used 10 per cent. of glycerin and stronger alcohol. It is used as an alterative and diuretic.

The dose is thirty minims (2 mils).

FLUIDEXTRACTUM PETROSELINI RADICIS. N. F.

Fluidextract of Parsley Root [Fldext. Petrosel. Rad.]

Prepared by using two volumes of alcohol and one volume of water as the menstruum. It is used as an emmenagogue and diuretic.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM PHYTOLACCÆ. N. F. (U. S. P. VIII)

Fluidextract of Phytolacca [Fldext. Phytolac.]

Prepared by using diluted alcohol, as directed by the U. S. P. VIII, as the menstruum. It is used as an emetic and alterative.

The *dose* is fifteen minims (1 mil) as an emetic, and one and one-half minims (0.1 mil) as an alterative.

FLUIDEXTRACTUM PRUNI VIRGINIANÆ. N. F. (U. S. P. VIII)

Fluidextract of Wild Cherry [Fldext. Prun. Virg.]

Prepared by using 200 mils of glycerin and 400 mils of water as the macerating menstruum, then percolating with a menstruum of 250 mils of alcohol and 150 mils of water and continuing with one volume of alcohol and three volumes of water as the menstruum. This process differs materially from that of the U. S. P. VIII. It is used as a cough sedative.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM QUASSIÆ. N. F. (U. S. P. VIII)

Fluidextract of Quassia [Fldext. Quass.]

Prepared by using one volume of alcohol and two volumes of water, as directed by the U. S. P. VIII, as the menstruum. This affords an excellent means of obtaining the effects of quassia. It has the advantage over the tincture of not requiring so large an amount of alcohol.

The *dose* is eight minims (0.5 mil).

FLUIDEXTRACTUM QUERCUS. N. F. (U. S. P. VIII)

Fluidextract of Quercus [Fldext. Querc.]

Prepared by using 100 mils of glycerin, 500 mils of alcohol and 400 mils of water as menstruum I, and diluted alcohol as menstruum II. Practically the same menstruum was used in the U. S. P. VIII.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM RHAMNI CATHARTICÆ. N. F.

Fluidextract of Rhamnus Cathartica [Fldext. Rham. Cathart.]

Prepared by using diluted alcohol as the menstruum. It is used as a cathartic.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM RHOIS GLABRÆ. N. F. (U. S. P. VIII)

Fluidextract of Rhus Glabra [Fldext. Rhois Glab.]

Prepared by using 100 mils of glycerin, 500 mils of alcohol, and 400 mils of water as menstruum I, and diluted alcohol as menstruum II. This is an excellent astringent, especially useful as a gargle because of its agreeable flavor.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM RUBI. N. F. (U. S. P. VIII)

Fluidextract of Rubus [Fldext. Rubi]

Prepared by using diluted alcohol, as directed by the U. S. P. VIII, as the menstruum. It is used as an intestinal astringent.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM RUMICIS. N. F.

Fluidextract of Rumex [Fldext. Rumic.]

Prepared by using diluted alcohol as the menstruum. It is feebly astringent.

The *dose* is one fluidrachm (4 mils).

FLUIDEXTRACTUM SANGUINARIÆ. N. F. (Replacing U. S. P. VIII)

Fluidextract of Sanguinaria [Fldext. Sanguin.]

Prepared by using 100 Gm. of citric acid dissolved in enough water to make 250 mils, and 750 mils of alcohol as menstruum I, and three volumes of alcohol and one volume of water as menstruum II—the U. S. P. VIII directed the use of dilute acetic acid as the menstruum for this fluidextract. It is used as a nauseating expectorant.

The *dose* is one and one-half minims (0.1 mil).

FLUIDEXTRACTUM SCOPARII. N. F.

Fluidextract of Scoparius [Fldext. Scopar.]

Prepared by using diluted alcohol as the menstruum. It is used as a diuretic and purgative.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM SCUTELLARIÆ. N. F. (U. S. P. VIII)

Fluidextract of Scutellaria [Fldext. Scutellar.]

Prepared by using diluted alcohol, as directed by the U. S. P. VIII, as the menstruum. It has no medicinal value.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM SENECIONIS. N. F.

Fluidextract of Senecio [Fldext. Senecion.]

Prepared by using two volumes of alcohol and one volume of water as the menstruum. It is believed by some to possess emmenagogue powers.

The *dose* is one fluidrachm (4 mils).

FLUIDEXTRACTUM SERPENTARIÆ. N. F. (U. S. P. VIII)

Fluidextract of Serpentaria [Fldext. Serpentar.]

Prepared by using four volumes of alcohol and one volume of water, as directed by the U. S. P. VIII, as the menstruum. It is used as a tonic and antiperiodic.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM SOLANI. N. F.

Fluidextract of Solanum [Fldext. Solan.]

Prepared by using two volumes of alcohol and one volume of water as the menstruum. It is used as an antispasmodic and aphrodisiac.

The *dose* is one fluidrachm (4 mils).

FLUIDEXTRACTUM STILLINGIÆ COMPOSITUM. N. F.

Compound Fluidextract of Stillingia [Fldext. Stilling. Co.]

Prepared by using alcohol, 500 mils, water, 250 mils, glycerin, 250 mils, finishing with diluted alcohol. It contains stillingia, corydalis, iris, sambucus, chimaphila, coriander, and xanthoxylum berries. It is a relic of therapeutic superstition.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM STRAMONII. N. F. (U. S. P. VIII)

Fluidextract of Stramonium [Fldext. Stramon.]

One hundred millilitres of fluidextract of stramonium yields not less than 0.22 Gm. nor more than 0.28 Gm. of the alkaloids of stramonium. Prepared by using two volumes of alcohol and one volume of water, as directed by the U.

S. P. VIII, as the menstruum. It is used as a sedative and analgesic. An assay is provided in the text.

The *dose* is one minim (0.05 mil).

FLUIDEXTRACTUM THUJÆ. N. F.

Fluidextract of Thuja [Fldext. Thuj.]

Prepared by using alcohol as the menstruum. It is used as a stimulating expectorant and diuretic.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM THYMI. N. F.

Fluidextract of Thyme [Fldext. Thym.]

Prepared by using 100 mils of glycerin, 250 mils of alcohol and 650 mils of water as menstruum I, and one volume of alcohol and three volumes of water as menstruum II. It is used as a carminative and antispasmodic, but is inferior in value to the oil.

The *dose* is one fluidrachm (4 mils).

FLUIDEXTRACTUM TRIFOLII. N. F.

Fluidextract of Trifolium [Fldext. Trifol.]

Prepared by using diluted alcohol as the menstruum. It is used as an alterative and antispasmodic.

The *dose* is one fluidrachm (4 mils).

FLUIDEXTRACTUM TRILLII. N. F.

Fluidextract of Trillium [Fldext. Trill.]

Prepared by using three volumes of alcohol and one volume of water as the menstruum. It is used as an astringent and tonic expectorant.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM VALERIANÆ. N. F. (U. S. P. VIII)

Fluidextract of Valerian [Fldext. Valer.]

Prepared by using four volumes of alcohol and one volume of water as the menstruum—the U. S. P. VIII used three volumes of alcohol and one volume of water as the menstruum. It is used as a sedative and antispasmodic.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM VERBASCI FOLIORUM. N. F.

Fluidextract of Mullein Leaves [Fldext. Verbasc. Fol.]

Prepared by using diluted alcohol as the menstruum. It is used as a demulcent.

The *dose* is one fluidrachm (4 mils).

FLUIDEXTRACTUM VERBENÆ. N. F.

Fluidextract of Verbena [Fldext. Verben.]

Prepared by using diluted alcohol as the menstruum. It is used as a tonic.

The *dose* is fifteen minims (1 mil).

FLUIDEXTRACTUM VIBURNI OPULI. N. F.

Fluidextract of Viburnum Opulus [Fldext. Viburn. Opul.]

Prepared by using two volumes of alcohol and one volume of water as the menstruum. It is used as a nerve sedative.

The *dose* is thirty minims (2 mils).

FLUIDEXTRACTUM ZEÆ. N. F.

Fluidextract of Zea [Fldext. Zea.]

Made with diluted alcohol. It is used as a diuretic.

The *dose* is one fluidrachm (4 mils).

FLUIDGLYCERATA. N. F.

Fluidglycerates

Fluidglycerates are intended to be of the same drug strength as fluidextracts. They contain approximately 50 per cent., by volume, of glycerin and no alcohol. Fluidglycerates made from drugs that do not require either an acid or an alkaline menstruum may be prepared by a general process which embodies maceration, percolation, and evaporation to a given volume. The preparation is then allowed to stand for a few days, and the clear portion decanted and the remainder strained.

FLUIDGLYCERATUM CASCARÆ SAGRADÆ. N. F.

Fluidglycerate of Cascara Sagrada [Fldglycer. Casc. Sagr.]

Prepared from cascara sagrada according to the general process.

The *dose* is fifteen minims (1 mil).

FLUIDGLYCERATUM CASCARÆ SAGRADÆ AROMATICUM. N. F.

Aromatic Fluidglycerate of Cascara Sagrada [Fldglycer. Casc. Sagr. Arom.]

Prepared from cascara sagrada by removing its bitter taste with calcium oxide and subsequently flavoring with fluidglycerate of licorice and oils of fennel, clove, and cinnamon.

The *dose* is fifteen minims (1 mil).

FLUIDGLYCERATUM GLYCYRRHIZÆ. N. F.

Fluidglycerate of Glycyrrhiza [Fldglycer. Glycyrrh. Fluidglycerate of Licorice]

Prepared from glycyrrhiza (licorice) by the general process, the glycerin and water men-

struum being rendered slightly alkaline with ammonia water. It is used as a demulcent and vehicle.

The *dose* is thirty minims (2 mils).

FLUIDGLYCERATUM KRAMERIÆ. N. F.

Fluidglycerate of Krameria [Fldglycer. Kramer.]

Prepared from krameria by the general process. It is used as an astringent and hemostatic.

The *dose* is fifteen minims (1 mil).

FLUIDGLYCERATUM RHEI. N. F.

Fluidglycerate of Rhubarb [Fldglycer. Rhei]

Prepared from rhubarb by the general process. It is used as a cathartic.

The *dose* is fifteen minims (1 mil).

GARGARISMA GUAIACI COMPOSITUM. N. F.

Compound Gargle of Guaiac [Garg. Guaiac. Co.]

This gargle contains 10 per cent. each of ammoniated tincture of guaiac and compound tincture of cinchona, 20 per cent. of clarified honey, and 4 per cent. of potassium chlorate, and oil of peppermint enough to flavor. Used as a local stimulant for the throat.

GELATINUM CHONDRI. N. F.

Chondrus Gelatin [Gelat. Chondr. Irish Moss Gelatin]

Prepared from chondrus by decoction, straining while hot, evaporating carefully to proper consistence, and "scaling" in shallow trays. It is used to make a transparent mucilage which is demulcent and nutritive.

GLYCERITUM BISMUTHI. N. F.

Glycerite of Bismuth [Glycer. Bism.]

One hundred millilitres of glycerite of bismuth yields not less than 12.8 Gm. of bismuth oxide. It is made from bismuth subnitrate, nitric acid, tartaric acid, sodium bicarbonate, glycerin, and distilled water. It contains 16 grains of bismuth and sodium tartrate in 1 fluidrachm of the finished glycerite, equivalent to 12.8 Gm. of bismuth oxide in 100 mils of glycerite, and is used in making other preparations containing bismuth. An assay is provided in the text.

GLYCERITUM GUAIACI. N. F.

Glycerite of Guaiac [Glycer. Guaiac.]

It contains 5 grains of guaiac and about 4 minims of solution of potassium hydroxide in 1 fluidrachm of the finished glycerite. It is used as an alterative.

The *dose* is thirty minims (2 mils).

GLYCERITUM PEPSINI. N. F.

Glycerite of Pepsin [Glycer. Pepsin.]

Five grains of pepsin are represented by 1 fluidrachm of the finished glycerite. The menstruum is acidulated water and glycerin. It is used as a digestive.

The *dose* is forty-five minims (3 mils).

GLYCERITUM PICIS LIQUIDÆ. N. F.

Glycerite of Tar [Glycer. Pic. Liq.]

This glycerite is made from tar, magnesium carbonate, glycerin, alcohol and water. The medicinal virtues of about 4 grains of tar are represented in 1 fluidrachm of the finished glycerite. It is used as an expectorant.

The *dose* is one fluidrachm (4 mils).

GLYCERITUM TRAGACANTHÆ. N. F.

Glycerite of Tragacanth [Glycer. Trag.]

This glycerite contains about 12.5 per cent. of tragacanth with glycerin and water. It is prepared in the form of a thick homogeneous paste. It is used as an excipient for pills.

GLYCERITUM VITELLI. N. F.

Glycerite of Egg Yolk [Glycer. Vitell. Glyconin]

This is a mixture of egg yolk, 45 per cent., and glycerin, 55 per cent. Used as an emsulsifying agent.

GLYCEROGELATINA. N. F.

Glycerogelatins

Glycerogelatins originated with Dr. Unna and are soft masses which melt at the temperature of the body. They contain gelatin, glycerin, water and the medicament, and are used in *skin diseases.*

GLYCEROGELATINUM ACIDI SALICYLICI. N. F.

Salicylic Acid Glycerogelatin [Glycerogel. Acid. Salicyl.]

This preparation contains 35 per cent. of glycerin and 10 per cent. of salicylic acid in glycerinated gelatin vehicle. Used as an antiseptic and keratoplastic.

GLYCEROGELATINUM IODOFORMI. N. F.

Iodoform Glycerogelatin [Glycerogel. Iodof.]

This preparation contains 15 per cent. of glycerin, and 10 per cent. of iodoform in glyce-

erinated gelatin vehicle. Used as an antiseptic dressing.

GLYCEROGELATINUM ZINCI DURUM. N. F.

Firm Zinc Glycerogelatin [Glycerogel. Zinc. Dur.]

This preparation contains 25 per cent. of glycerin, and 10 per cent. of zinc oxide in 30 per cent. glycerinated gelatin vehicle. Used as a local sedative and protective.

GLYCEROGELATINUM ZINCI MOLLE. N. F.

Soft Zinc Glycerogelatin [Glycerogel. Zinc. Mol.]

This preparation contains 35 per cent. of glycerin and 10 per cent of zinc oxide in 20 per cent. of glycerinated gelatin vehicle. Used as an astringent and protective.

GOSSYPIUM STYPTICUM. N. F.

Styptic Cotton [Gossyp. Stypt.]

It is made by impregnating purified cotton with diluted solution of ferric chloride, glycerin and water. It should be kept in well closed containers. It is used as a local styptic.

INFUSUM BRAYERÆ. N. F.

Infusum of Brayera [Inf. Brayer.]

This infusion which must be freshly prepared is made with 6 per cent. of the drug in boiling water.

The *dose* is eight fluidounces (250 mils).

INFUSUM CINCHONÆ. N. F.

Infusion of Cinchona [Inf. Cinchon.]

Made with 6 per cent. cinchona and cold acidulated water.

The *dose* is twelve fluidrachms (50 mils).

INFUSUM GENTIANÆ COMPOSITUM. N. F.

Compound Infusion of Gentian [Inf. Gent. Co.]

This elixir contains 3 per cent. of gentian, flavored with coriander, and bitter orange peel. It is used as a tonic, and is made by percolation.

The *dose* is four fluidrachms (15 mils).

INFUSUM PRUNI VIRGINIANÆ. N. F. (U. S. P. VIII)

Infusion of Wild Cherry [Inf. Prun. Virg.]

This well-known infusion is made with 40 grammes of wild cherry to 1000 mils by cold percolation and is preserved with glycerin. The U. S. P. VIII process was not changed.

The *dose* is two fluidounces (60 mils).

INFUSUM ROSÆ COMPOSITUM. N. F.

Compound Infusion of Rose [Inf. Ros. Co.]

This preparation which deserves a larger use on account of its pleasant flavor and beautiful color is made from red rose, diluted sulphuric acid, sugar and water. It is used as an astringent.

The *dose* is three fluidounces (100 mils).

INUNCTUM MENTHOLIS. N. F.

Menthol Inunction [Inunct. Menthol.]

This is a new preparation containing 5 per cent. of menthol incorporated with hydrous wool fat. It is used as a local anodyne and antipruritic.

INUNCTUM MENTHOLIS COMPOSITUM. N. F.

Compound Menthol Inunction [Inunct. Menthol. Co.]

This is another new preparation containing 5 per cent. of menthol and 10 per cent. of methyl salicylate in hydrous wool fat. It is counter-irritant as well as locally anesthetic.

IODOFORMUM AROMATISATUM. N. F.

Aromatized Iodoform [Iodof. Arom.]

This preparation consists of iodoform containing 4 per cent. of cumarin, and is used as an antiseptic and alterative.

LAC FERMENTATUM. N. F.

Fermented Milk [Lac. Ferment. Kumyss]

This well known dietetic preparation is made from fresh cow's milk, compressed yeast, and sugar, properly fermented, and is used as a food for invalids.

The *dose* is eight fluidounces (250 mils).

LINIMENTUM ACONITI ET CHLOROFORMI. N. F.

Liniment of Aconite and Chloroform [Lin. Aconit. et Chlorof.]

This preparation contains 4.5 per cent. fluidextract of aconite and 12.5 per cent. of chloroform in a mixture of alcohol and soap liniment. It is used externally to relieve pain.

LINIMENTUM AMMONII IODIDI. N. F.

Liniment of Ammonium Iodide [Lin. Ammon. Iod.]

This liniment is made from iodine, oil of rosemary, oil of lavender, camphor, ammonia water, and alcohol. It is used as an external discutient application.

LINIMENTUM OPII COMPOSITUM. N. F.

Compound Liniment of Opium [Lin. Opii Co. Canada Liniment]

This liniment contains 10 per cent. of tincture of opium, 22 per cent. of oil of turpentine and 35 per cent. of ammonia water, with camphor, alcohol and oil of peppermint, made into a somewhat permanent emulsion with fresh egg albumen. It is used as a stimulating anodyne application.

LINIMENTUM SAPONATO-CAMPHORATUM. N. F.

Camphorated Soap Liniment [Lin. Sapon.-Camph. Solid Opodeldoc]

This liniment contains freshly prepared sodium stearate made by combining monohydrated sodium carbonate and stearic acid, camphor, alcohol, oils of thyme and rosemary and ammonia water. It is a useless survival of a former fad.

LINIMENTUM SAPONIS MOLLIS COMPOSITUM. N. F.

Tinctura Saponis Viridis Composita, N. F. III. Compound Liniment of Soft Soap [Lin. Sapon. Mol. Co.]

There is no change in this preparation which was formerly classed as compound tincture of green soap. It contains soft soap, oil of cade, and alcohol.

LINIMENTUM SINAPIS COMPOSITUM. N. F.

Compound Liniment of Mustard [Lin. Sinap. Co.]

This is a new preparation consisting of 3 per cent. of volatile oil of mustard, with fluidextract of mezereum, camphor, castor oil, and alcohol. It is an active rubefacient.

LINIMENTUM TEREBINTHINÆ ACETICUM. N. F.

Acetic Turpentine Liniment [Lin. Terebinth. Acet. Linimentum Album. Stokes' Liniment. St. John Long's Liniment]

This liniment contains 40 per cent. of oil of turpentine, fresh egg, oil of lemon, acetic acid and rose water. It is a powerful counter-irritant.

LINIMENTUM TIGLII. N. F.

Liniment of Croton Oil [Lin. Tiglii. Linimentum Crotonis]

This liniment contains 13 volumes of croton oil, and 44 volumes of alcohol, and 43 volumes of oil of cajuput. It is used as a pustulant counter-irritant.

LINIMENTUM TIGLII COMPOSITUM. N. F.

Compound Croton Oil Liniment [Lin. Tiglii Co.]

This liniment contains 20 per cent. each of croton oil, oil of sassafras, oil of turpentine, with 40 per cent. of olive oil. It is an active pustulant and counter-irritant and should be used with circumspection.

LIQUOR ALUMINI ACETATIS. N. F.

Solution of Aluminum Acetate [Liq. Alum. Acet. Liquor Burowii. Burow's Solution]

One hundred millilitres of this solution contains not less than 4.5 and not more than 5.5 Gm. of neutral aluminum acetate [$Al(C_2H_3O_2)_3 = 204.17$]. It is made by the reactions between lead acetate and aluminum sulphate in aqueous solution. A process of assay is also given in the text. It should be noted that this differs from the solution of aluminum acetate of the N. F. III which is now known as the solution of the subacetate. It is astringent and antiseptic.

LIQUOR ALUMINI ACETICO-TARTRATIS. N. F.

Solution of Aluminum Acetico-Tartrate [Liq. Alum. Acet.-Tart.]

This solution contains about 50 per cent. of dry so-called aluminum acetico-tartrate. It is made from ammonium, alum, monohydrated sodium carbonate, tartaric acid, glacial acetic acid, and water, and used externally as an astringent and disinfectant. It should be diluted when used for medicinal purposes.

LIQUOR ALUMINI SUBACETATIS. N. F.

Liquor Alumini Acetatis, N. F. III. Solution of Aluminum Subacetate [Liq. Alum. Subacet.]

This solution is made from aluminum sulphate, acetic acid, precipitated calcium carbonate and water, and contains from 7.5 to 8 per cent. of basic aluminum acetate. An assay

process is also given in the text. This preparation corresponds closely to the *Liquor Alumini Acetici* of the German Pharmacopœia. It is an active germicide, as well as astringent, and is used both as a gargle and as a surgical dressing. It should generally be diluted with from 4 to 8 parts of water.

LIQUOR AMMONII CITRATIS. N. F.

Solution of Ammonium Citrate [Liq. Ammon. Cit.]

This preparation must not be confused with the Liquor Ammonii Citratis Fortior which was formerly official. It is made by cautiously neutralizing 125 Gm. of citric acid with ammonia water and then making up to a volume of 1000 mils with distilled water. It is used as a refrigerant and diuretic.

The *dose* is one fluidrachm (4 mils).

LIQUOR ANTISEPTICUS. N. F. (Replacing U. S. P. VIII)

Antiseptic Solution [Liq. Antisept.]

This preparation which replaces the Liquor Antisepticus of the U. S. P. VIII, contains about the same ingredients as the former preparation, but is much pleasanter in taste and less harsh in effect. While it possesses feeble antiseptic properties, it is chiefly useful to flavor mouth-washes.

LIQUOR ANTISEPTICUS ALKALINUS. N. F.

Alkaline Antiseptic Solution [Liq. Antisept. Alk.]

This solution is made from potassium bicarbonate, sodium benzoate, sodium borate, thymol, eucalyptol, oil of peppermint, methyl salicylate, cudbear, alcohol, glycerin, magnesium carbonate and water. It is used as an alkaline antiseptic and feeble detergent.

LIQUOR ARSENICALIS, CLEMENS. N. F.

Liquor Potassii Arsenatis et Bromidi, N. F. III. Clemens' Solution of Arsenic [Solution of Potassium Arsenate and Bromide. Liq. Arsen., Clemens]

An aqueous solution containing an amount of arsenic in combination, corresponding to about 1 per cent. of arsenic trioxide [As_2O_3]. This preparation is made from arsenic trioxide, potassium bicarbonate, bromine and water. It is used as an alterative.

The *dose* is three minims (0.2 mil).

LIQUOR AURI ET ARSENI BROMIDI. N. F.

Solution of Gold and Arsenic Bromide [Liq. Aur. et Arsen. Brom.]

This preparation represents about 1-32d of a grain of tribromide of gold and 1-13th of a grain of tribromide of arsenic, in each ten minims. It is used as an alterative.

The *dose* is three minims (0.2 mil).

LIQUOR BISMUTHI. N. F.

Solution of Bismuth [Liq. Bism.]

This solution is made from glycerite of bismuth, alcohol, and distilled water. About 1 grain of bismuth and sodium tartrate is represented in 1 fluidrachm of the finished solution. It is used as an intestinal astringent, but does not possess the therapeutic virtues of the insoluble bismuth salts.

The *dose* is one fluidrachm (4 mils).

LIQUOR BROMI. N. F.

Solution of Bromine [Liq. Brom. Smith's Solution of Bromine]

One hundred mils of finished solution contains 8.3 mils of bromine and 12.5 grammes of potassium bromide. It is a powerful germicide and was formerly used extensively as an application in *gangrene*.

LIQUOR CALCIS SULPHURATÆ. N. F.

Solution of Sulphurated Lime [Liq. Calc. Sulphurat. Solution of Oxysulphuret of Calcium Vleminckx' solution. Vleminckx' Lotion]

This solution is made by boiling together lime, sublimed sulphur and water. It is used as an external application in skin diseases.

LIQUOR CARMINI. N. F.

Solution of Carmine [Liq. Carmin.]

This solution is made from carmine, ammonia water, glycerin and water. It is used as a red coloring solution.

LIQUOR CHLORI COMPOSITUS. N. F. (Replacing U. S. P. VIII)

Compound Solution of Chlorine [Liq. Chlor. Co. Chlorine Water]

This is an aqueous solution containing, when freshly made, a mixture of chlorine and chlorine oxides equivalent to about 0.35 Gm. of available chlorine in each one hundred millilitres of the solution, with some potassium chloride. It is made by reacting upon potassium chlorate with hydrochloric acid and then dissolving the products of the reaction in cold

distilled water; this is practically identical with the U. S. P. VIII process. It is used as an intestinal antiseptic.

The *dose* is one fluidrachm (4 mils).

LIQUOR COCCI. N. F.

Liquor Coccineus, N. F. III

Cochineal Color [Liq. Cocci]

This solution is made from cochineal, potassium carbonate, alum, potassium bitartrate, alcohol, glycerin, and water. Like the solution of carmine, it is used to color preparations red.

LIQUOR FERRI ACETATIS. N. F.

Solution of Ferric Acetate [Liq. Ferr. Acet.]

This is an aqueous solution containing about 31 per cent. of anhydrous ferric acetate [$Fe(C_2H_3O_2)_3 = 232.91$], corresponding to about 7.5 per cent. metallic iron (Fe). It is made from solution of ferric sulphate, glacial acetic acid, ammonia water, and distilled water. An assay process is given in the text.

The *dose* is five minims (0.3 mil).

LIQUOR FERRI ALBUMINATI. N. F.

Solution of Albuminate of Iron [Liq. Ferr. Albumin.]

This solution is made from fresh egg-albumen, solution of ferric oxychloride, alcohol, sodium citrate, aromatic elixir, and water. About 2-5th of a grain of metallic iron in the form of albuminate is contained in 1 fluidrachm of the finished solution. It is used as a chalybeate.

The *dose* is two fluidrachms (8 mils).

LIQUOR FERRI CITRATIS. N. F.

Solution of Ferric Citrate [Liq. Ferr. Cit.]

This solution is an aqueous solution containing ferric citrate corresponding to not less than 7.25 per cent. of metallic iron (Fe). It is made from solution of ferric sulphate, citric acid, ammonia water, and water. A process of assay is given in the text.

The *dose* is ten minims (0.6 mil).

LIQUOR FERRI HYPOPHOSPHITIS. N. F.

Solution of Ferric Hypophosphite [Liq. Ferr. Hypophos. Solution of Hypophosphite of Iron]

This preparation is made from ferric hypophosphite made soluble by the use of potassium citrate and dissolved in glycerin and water. About 10 grains of ferric hypophosphite are represented in 1 fluidrachm of finished solution.

The *dose* is fifteen minims (1 mil).

LIQUOR FERRI NITRATIS. N. F.

Solution of Ferric Nitrate [Liq. Ferr. Nit.]

This preparation is an aqueous solution containing ferric nitrate [$Fe(NO_3)_3 = 241.87$] corresponding to not less than 1.3 per cent. of metallic iron (Fe). It is made from solution of ferric sulphate, ammonia water, nitric acid, and distilled water. A process of assay is given in the text.

The *dose* is five minims (0.3 mil).

LIQUOR FERRI OXYCHLORIDI. N. F.

Solution of Ferric Oxychloride [Liq. Ferr. Oxychlor.]

This preparation is intended to replace the former dialyzed iron. It is made from solution of ferric chloride, ammonia water, glycerin, hydrochloric acid, and water. It contains about 3.5 per cent. of iron as oxychloride, and is used as a chalybeate.

The *dose* is thirty minims (2 mils).

LIQUOR FERRI OXYSULPHATIS. N. F.

Solution of Ferric Oxysulphate [Liq. Ferr. Oxysulph.]

This solution is made from ferrous sulphate, nitric acid, and distilled water.

LIQUOR FERRI PEPTONATI. N. F.

Solution of Peptonate of Iron [Liq. Ferr. Pepton.]

It is made from pepsin, fresh egg albumen, hydrochloric acid, solution of ferric oxychloride, alcohol, and sodium citrate made up into a pleasantly flavored preparation with oil of orange, acetic ether, and vanillin, using glycerin, syrup and distilled water. It contains about $\frac{1}{5}$ of a grain of metallic iron, in the form of peptonate, in 1 fluidrachm of the finished solution. It is used as a chalybeate.

The *dose* is two fluidrachms (8 mils).

LIQUOR FERRI PEPTONATI ET MANGANI. N. F.

Liquor Ferri Peptonati cum Mangano, N. F. III. Solution of Peptonate of Iron and Manganese [Liq. Ferr. Pepton. et Mangan.]

This preparation is made from the same ingredients and in a similar manner to the foregoing preparation with the addition of solu-

ble manganese citrate. It is used as a chalybeate and alterative.

The *dose* is two fluidrachms (8 mils).

LIQUOR FERRI PROTOCHLORIDI. N. F.

Solution of Ferrous Chloride [Liq. Ferr. Protochlor. Solution of Protochloride of Iron.]

This solution is made from iron wire, hydrochloric acid, glycerin, diluted hypophosphorous acid and distilled water. About 20 grains of ferrous chloride are represented by 1 fluidrachm of finished solution. It is used as a chalybeate tonic and as an astringent.

The *dose* is ten minims (0.6 mil).

LIQUOR FERRI SALICYLATIS. N. F.

Solution of Ferric Salicylate [Liq. Ferr. Salicyl. Salicylated Mixture of Iron]

This is a new preparation, containing sodium salicylate, tincture of ferric citrochloride, ammonium carbonate, citric acid, methyl salicylate, glycerin, and distilled water. Each fluidrachm is equivalent to about 7½ grains of sodium salicylate and 7½ minims of Tincture of Ferric Citro-Chloride. It has been recommended for cases of chronic rheumatism complicated with anæmia.

The *dose* is two fluidrachms (8 mils).

LIQUOR GUTTÆ PERCHÆ. N. F.

Solution of Gutta Percha [Liq. Gut. Perch.]

This is a solution of gutta percha in chloroform, clarified by the addition of lead carbonate. It is used externally as a protection.

LIQUOR HYDRARGYRI ET POTASSII IODIDI N. F.

Solution of Mercury and Potassium Iodide [Liq. Hydrarg. et Pot. Iod. Solution of Potassium Iodohydrargyrate. Channing's Solution]

This preparation represents about 1 per cent. of red iodide of mercury and 0.8 per cent. of potassium iodide in aqueous solution. It is used as an alterative in the treatment of *syphilis*.

The *dose* is three minims (0.2 mil).

LIQUOR HYDRARGYRI NITRATIS. N. F. (U. S. P. VIII)

Solution of Mercuric Nitrate [Liq. Hydrarg. Nit.]

This is an aqueous solution containing not less than 58 per cent. nor more than 62 per cent. of anhydrous mercuric nitrate [$Hg(NO_3)_2$ = 324.62] and about 11 per cent. of free nitric acid. It is made by dissolving red mercuric oxide in a mixture of nitric acid and distilled water. The process is the same as that of the U. S. P. VIII. It is used locally as a caustic and disinfectant. An assay process is given in the text.

LIQUOR HYDRASTINÆ COMPOSITUS. N. F.

Compound Solution of Hydrastine [Liq. Hydrastin. Co. Colorless Hydrastine Solution]

This is a new preparation containing 0.3 per cent. of hydrastine hydrochloride with the chlorides of aluminum, calcium, magnesium, and potassium in solution in glycerin and water. Its therapeutic virtues are solely those of hydrastine.

The *dose* is one fluidrachm (4 mils).

LIQUOR HYPOPHOSPHITUM. N. F.

Solution of Hypophosphites [Liq. Hypophos.]

This preparation contains 2 grains of calcium hypophosphite, 1¼ grains of sodium hypophosphite and 1 grain of potassium hypophosphite in 1 fluidrachm of finished solution. It is used as an alterative and tonic.

The *dose* is one fluidrachm (4 mils).

LIQUOR HYPOPHOSPHITUM COMPOSITUS. N. F.

Compound Solution of Hypophosphites [Liq. Hypophos. Co.]

This solution is made from calcium, potassium, sodium, ferric, manganese and quinine hypophosphites, strychnine, potassium citrate, hypophosphorous acid, orange flower water, glycerin, and distilled water. It is used as an alterative and tonic.

The *dose* is one fluidrachm (4 mils).

LIQUOR IODI PHENOLATUS. N. F. Liquor Iodi Carbolatus, N. F. III

Phenolated Solution of Iodine [Liq. Iod. Phenol. Carbolized Solution of Iodine. Boulton's Solution. French Mixture]

This solution is made from compound solution of iodine, liquefied phenol, glycerin, and water. It is used externally.

LIQUOR MAGNESII SULPHATIS EFFERVESCENS. N. F.

Effervescent Solution of Magnesium Sulphate [Liq. Mag. Sulph. Eff.]

This preparation contains about 385 grains of magnesium sulphate in 12 fluidounces of the

finished solution. It is used as a cathartic, like solution of magnesium citrate.

The *dose* is the entire contents of the bottle prepared as directed; about twelve fluidounces (350 mils).

LIQUOR PANCREATINI. N. F. Liquor Pancreaticus, N. F. III

Solution of Pancreatin [Liq. Pancreat. Pancreatic Solution]

This solution is made from pancreatin, sodium bicarbonate, glycerin, compound spirit of cardamom, alcohol, purified talc and water. about 1 grain of pancreatin is represented in 1 fluidrachm of the finished solution. It is used as a digestive.

The *dose* is one fluidrachm (4 mils).

LIQUOR PEPSINI. N. F.

Solution of Pepsin [Liq. Pepsin.]

This solution contains glycerite of pepsin, hydrochloric acid, glycerin and water. It is used as a digestive.

The *dose* is two fluidrachms (8 mils).

LIQUOR PEPSINI ANTISEPTICUS. N. F.

Antiseptic Solution of Pepsin [Liq. Pepsin. Antisept.]

This is a new preparation containing pepsin, hydrochloric acid, menthol, eucalyptol, and methyl salicylate in solution in glycerin, alcohol and water. It is used externally in the treatment of old sores to assist their healing.

LIQUOR PEPSINI AROMATICUS. N. F.

Aromatic Solution of Pepsin [Liq. Pepsin. Arom.]

This solution is made from pepsin, oils of cinnamon, pimenta and clove, and alcohol, hydrochloric acid, glycerin and water. About 1 grain of pepsin is represented in 1 fluidrachm of finished solution. It is used as a digestive.

The *dose* is two fluidrachms (8 mils).

LIQUOR PHOSPHATUM ACIDUS. N. F.

Acid Solution of Phosphates [Liq. Phos. Acid. Solution of Acid Phosphates]

This was formerly a solution of acid phosphates made by adding sulphuric acid and water to bone ash, expressing and filtering. It is now made by dissolving calcium and magnesium carbonate in phosphoric acid and water.

The *dose* is one fluidrachm (4 mils).

LIQUOR PHOSPHATUM COMPOSITUS. N. F.

Compound Solution of Phosphates [Liq. Phos. Co.]

This is a polypharmacal preparation containing the phosphates of ammonium, calcium, iron, potassium, and sodium held in aqueous solution by the use of glycerin and citric acid. It is flavored with orange flower water.

LIQUOR PHOSPHORI. N. F.

Solution of Phosphorous [Liq. Phosphor. Thompson's Solution of Phosphorus]

This solution is made from phosphorus, dehydrated alcohol, spirit of peppermint and glycerin. About 1-24th of a grain of phosphorus is contained in 1 fluidrachm of finished solution. It is used as a tonic and stimulant in nervous diseases.

The *dose* is ten minims (0.6 mil).

LIQUOR PICIS ALKALINUS. N. F.

Alkaline Solution of Tar [Liq. Pic. Alk.]

This solution contains about 25 per cent. of tar and 12.5 per cent. of potassium hydroxide in water. It is used in skin diseases as an external application.

LIQUOR PICIS CARBONIS. N. F.

Coal Tar Solution [Liq. Pic. Carbon.]

This preparation, sometimes known by the name of *Liquor Carbonis Detergens,* is made by digesting 200 Gm. of coal tar and 100 Gm. of soap bark with enough alcohol to make 1000 mils. It is used externally in skin diseases.

LIQUOR POTASSÆ CHLORINATÆ. N. F.

Solution of Chlorinated Potassa [Liq. Pot. Chlorinat. Liquor Potassæ Chloratæ. Javelle Water]

This preparation which is analogous to Labarraque's solution is made from potassium carbonate, chlorinated lime, and water. It is used as a disinfectant.

LIQUOR SODÆ ET MENTHÆ. N. F. Mistura Sodæ et Menthæ, N. F. III

Solution of Soda and Mint [Liq. Sod. et Menth. Soda Mint]

This preparation contains sodium bicarbonate, aromatic spirit of ammonia and spearmint or peppermint water. Each fluidrachm contains 3 grains of the bicarbonate and 0.6 minim of aromatic spirit of ammonia. It is used as an antacid and carminative.

The *dose* is two fluidrachms (8 mils).

LIQUOR SODII ARSENATIS, PEARSON. N. F.

Pearson's Solution of Sodium Arsenate [Liq. Sod. Arsen., Pearson. Liquor Arsenicalis Pearsonii]

This preparation should not be confounded with the Liquor Sodii Arsenatis, U. S. P., which is ten times stronger than Pearson's solution. It contains about 1-6th per cent. of crystallized sodium arsenate or about 1-10th per cent. of anhydrous sodium arsenate. Whenever it is prescribed or dispensed, the name "Pearson" should be specified, to avoid serious mistakes. It is used as an alterative.

The *dose* is thirty minims (2 mils).

LIQUOR SODII BORATIS COMPOSITUS. N. F.

Compound Solution of Sodium Borate [Liq. Sod. Bor. Co. Dobell's Solution]

This solution contains about 1.5 per cent. each of sodium borate and sodium bicarbonate and 0.3 per cent. of phenol, with glycerin and water. It is widely used as a cleansing wash in inflammations of the nose and pharynx.

LIQUOR SODII CITRATIS. N. F.

Solution of Sodium Citrate [Liq. Sod. Cit. Mistura Sodii Citratis. Potio Rivierii]

This solution is made with 2 per cent. of citric acid and 2.5 per cent. of sodium bicarbonate in distilled water. It should be freshly prepared. The amount of sodium citrate formed, about 1.6 grains for each fluidrachm, is so small that the solution has scarcely any effect beyond that of a mildly saline drink.

The *dose* is two fluidrachms (8 mils).

LIQUOR SODII CITRO-TARTRATIS EFFERVESCENS. N. F.

Effervescent Solution of Sodium Citro-Tartrate [Liq. Sod. Citro.-Tart. Eff.]

This solution is made from sodium bicarbonate, tartaric acid, citric acid, syrup of citric acid and water. It is directed that this solution be dispensed in a tightly-stoppered bottle, containing 350 mils (12 fluidounces), while still effervescent. It is a pleasant, acidulous, feeble laxative; the contents of one bottle are equivalent in action to about one-third of a pair of Seidlitz powders.

LIQUOR SODII PHOSPHATIS COMPOSITUS. N. F. (Replacing U. S. P. VIII)

Compound Solution of Sodium Phosphate [Liq. Sod. Phos. Co.]

This preparation, which differs slightly from the U. S. P. VIII preparation of the same name, contains sodium phosphate crystals, citric acid, glycerin, and distilled water—the U. S. P. VIII formula contained 4 per cent. of sodium nitrate, which has been omitted in the N. F., while glycerin has been added. Each mil represents 1 gramme of crystallized sodium phosphate. It is used as a laxative.

The *dose* is two fluidrachms (8 mils).

LIQUOR STRYCHNINÆ ACETATIS. N. F.

Solution of Strychnine Acetate [Liq. Strych. Acet. Hall's Solution of Strychnine]

This preparation should not be confounded with the Liquor Strychninæ Hydrochloridi of the British Pharmacopœia, which is much stronger. Solution of strychnine acetate is made from strychnine, diluted acetic acid, alcohol, compound tincture of cardamom and water. About ⅛ of a grain of strychnine acetate is contained in 1 fluidrachm of the finished solution. It is used as a cardiac stimulant and tonic.

The *dose* is ten minims (0.6 mil).

LIQUOR ZINCI ET ALUMINI COMPOSITUS. N. F.

Compound Solution of Zinc and Aluminum [Liq. Zinc. et Alumin. Co.]

This preparation contains about 20 per cent. each, of zinc sulphate and aluminum sulphate, with betanaphthol, oil of thyme and water. It is used externally as an astringent and disinfectant.

LIQUOR ZINCI ET FERRI COMPOSITUS. N. F.

Compound Solution of Zinc and Iron [Liq. Zinc. et Ferr. Co. Deodorant Solution]

This preparation contains 20 per cent. each of zinc sulphate and ferrous sulphate, 6.5 per cent. of copper sulphate, with betanaphthol, oil of thyme, hypophosphorous acid and water. It is used as an antiseptic and astringent solution.

LOTIO AMMONIACALIS CAMPHORATA. N. F. Aqua Sedativa, N. F. III

Ammoniated Camphor Wash [Lot. Ammon. Camph. Sedative Water. Eau Sedative de Raspail]

This is an aqueous solution containing 6 per cent. each of sodium chloride and ammonia water, with 10 per cent. spirit of camphor.

LOTIO FLAVA. N. F.

Yellow Lotion [Lot. Flav. Yellow Wash. Aqua Phagedænica Flava]

It is made with 0.3 per cent. of corrosive mercuric chloride in lime water slightly diluted

with water. The mercury is present as a yellow hydroxide in the finished preparation. It is used externally in skin diseases. It is slightly weaker than the corresponding preparation of the Br. (See p. 668.)

LOTIO NIGRA. N. F.

Black Lotion [Lot. Nigr. Black Wash. Aqua Phagedænica Nigra]

It is made with 0.875 per cent. (formerly 0.75 per cent.) of mild mercurous chloride in lime water slightly diluted with water. The mercury is largely present as a black suboxide. It is used externally in skin diseases. It exceeds in strength the similar Br. preparation (see p. 668).

LOTIO PLUMBI ET OPII. N. F.

Lotion of Lead and Opium [Lot. Plumb. et Opii. Lead and Opium Wash]

It contains, in each 100 mils, 1.75 grammes of lead acetate and 3.5 grammes of tincture of opium. It is used as an astringent and sedative external application.

MAGMA FERRI HYDROXIDI. N. F. Ferri Hydroxidum, U. S. P. VIII

Ferric Hydroxide Magma [Magm. Ferr. Hydrox. Ferric Hydroxide]

This is a freshly precipitated well washed ferric hydroxide, made by decomposing solution of ferric sulphate with ammonia water. The U. S. P. VIII and N. F. IV formulas and processes are identical. It may be used as an arsenical antidote, but is inferior to the U. S. P. *Ferri Hydroxidum cum Magnesii Oxido.*

MASSA COPAIBÆ. N. F.

Mass of Copaiba [Mass. Copaib. Solidified Copaiba]

This is a combination of copaiba with a hydrated magnesium oxide reduced to a pilular consistence.

The *dose* is fifteen grains (1 Gm.).

MEL ROSÆ ET SODII BORATIS. N. F.

Honey of Rose and Sodium Borate [Mel. Ros. et Sod. Bor. Honey of Rose with Borax]

This preparation is made with borax, glycerin, and honey of rose. It is used as an astringent application.

MEL SODII BORATIS. N. F.

Honey of Sodium Borate [Mel. Sod. Bor. Mel Boracis. Honey and Borax]

This preparation is made with borax, glycerin, and clarified honey. It is used as a local application in sore throat.

MENTHOL CAMPHORATUM. N. F. Campho-Menthol, N. F. III

Camphorated Menthol [Menthol. Camph. Camphor and Menthol]

Equal parts by weight of camphor and menthol with a small proportion of alcohol added. Applied locally in *neuralgia.*

MISTURA ADSTRINGENS. N. F. Mistura Adstringens et Escharotica, N. F. III

Astringent Mixture [Mist. Adstring. Villate's Mixture]

This preparation is made from solution of lead subacetate, copper sulphate, zinc sulphate and diluted acetic acid. It should be well shaken before dispensing to insure the even distribution of the precipitated lead sulphate. It is used externally as an astringent and escharotic.

MISTURA AMMONII CHLORIDI. N. F.

Mixture of Ammonium Chloride [Mist. Ammon. Chlor. Mistura Solvens Simplex]

This preparation contains 1½ grains each of ammonium chloride and purified extract of glycyrrhiza in one fluidrachm of water. It is used as an expectorant.

The *dose* is two fluidrachms (8 mils).

MISTURA CAMPHORÆ ACIDA. N. F.

Acid Camphor Mixture [Mist. Camph. Acid. Mistura Antidysenterica. Hope's Mixture]

It contains 1.75 mils of nitric acid, 1.2 mils of tincture of opium in camphor water to make 100 mils. It is used in the treatment of serous *diarrheas.*

The *dose* is two fluidrachms (8 mils).

MISTURA CAMPHORÆ AROMATICA. N. F.

Aromatic Camphor Mixture [Mist. Camph. Arom. Parrish's Camphor Mixture]

It contains 25 mils of compound tincture of lavender, 3.5 mils of sugar, and camphor water to make 100 mils. It is used in *hysteria* and as a carminative.

The *dose* is two fluidrachms (8 mils).

MISTURA CARMINATIVA. N. F.

Carminative Mixture [Mist. Carminat. Dalby's Carminative]

It is made from magnesium carbonate, potassium carbonate, tincture of opium, oils of caraway, fennel, and peppermint, with syrup and water. About ⅛ of a grain of opium is

represented in 1 fluidrachm of the finished mixture. Its therapeutic effect is similar to that of paregoric.

The *dose* for an infant is eight minims (0.5 mil).

MISTURA CHLORALIS ET POTASSII BROMIDI COMPOSITA. N. F.

Compound Mixture of Chloral and Potassium Bromide [Mist. Chloral. et Pot. Brom. Co. Chloral and Bromide Compound]

This preparation represents about 12 grains each of hydrated chloral and potassium bromide, and ⅛ grain each of the extracts of Indian cannabis and hyoscyamus in each fluidrachm of the finished mixture. It is used as a somnifacient.

The *dose* is one fluidrachm (4 mils).

MISTURA CHLOROFORMI ET MORPHINÆ COMPOSITA. N. F.

Compound Mixture of Chloroform and Morphine [Mist. Chlorof. et Morph. Co. Mistura Chloroformi et Cannabis Indicæ Composita, N. F. III. Chloroform Anodyne]

This preparation contains chloroform, ether, tincture of Indian cannabis, tincture of capsicum, morphine sulphate, oil of peppermint, glycerin, water, and alcohol. About 7½ minims of chloroform, 11 minims of tincture of Indian cannabis, 2 minims of tincture of capsicum, 1-7th of a grain of morphine sulphate, are represented in 1 fluidrachm of the finished mixture. It is used in *diarrhea* and *cholera*. It should not be confounded with chlorodyne (see *Tinctura Chloroformi et Morphinæ Composita*, p. 1136), which is a much stronger preparation.

The *dose* is thirty minims (2 mils).

MISTURA COPAIBÆ. N. F.

Copaiba Mixture [Mist. Copaib. Lafayette Mixture]

This preparation contains copaiba, spirit of nitrous ether, compound tincture of lavender, solution of potassium hydroxide, syrup, and mucilage of acacia. There is 7½ minims each of copaiba and sweet spirit of nitre in one fluidrachm. It is used in *gonorrhea*.

The *dose* is two fluidrachms (8 mils).

MISTURA COPAIBÆ ET OPII. N. F.

Mixture of Copaiba and Opium [Mist. Copaib. et Opii. Chapman's Mixture]

This preparation contains double the proportions of copaiba and spirit of nitrous ether in the above, and in addition two minims of tincture of opium in each fluidrachm. It is used in *gonorrhea*.

The *dose* is one fluidrachm (4 mils).

MISTURA FERRI COMPOSITA. N. F. (U. S. P. VIII)

Compound Iron Mixture [Mist. Ferr. Co. Griffith's Mixture]

This preparation contains ferrous sulphate crystals, myrrh, sugar, potassium carbonate, spirit of lavender and rose water. The formula is the same as that of the U. S. P. VIII. It is a hæmatinic.

The *dose* is four fluidrachms (15 mils).

MISTURA GUAIACI. N. F.

Mixture of Guaiac [Mist. Guaiac.]

This preparation is made from tincture of guaiac, clarified honey, and cinnamon water. It is used as an alterative and expectorant. It is used in the treatment of *rheumatism*.

The *dose* is four fluidrachms (15 mils).

MISTURA MAGNESIÆ, ASAFŒTIDÆ ET OPII. N. F. Mistura Magnesiæ et Asafœtidæ, N. F. III

Mixture of Magnesia, Asafetida and Opium [Mist. Mag., Asafœt. et Opii. Dewees' Carminative]

This preparation contains 5 per cent. magnesium carbonate, 7.5 per cent. tincture of asafetida, 1 per cent. tincture of opium, with sugar and water. It is used as an anodyne and carminative.

The *dose* is two fluidrachms (8 mils).

MISTURA OLEI PICIS. N. F.

Mixture of Oil of Tar [Mist. Ol. Pic. Mistura Picis Liquidæ. Tar Mixture]

Each fluidrachm of this preparation contains approximately 2 minims of rectified oil of tar in a vehicle composed of purified extract of glycyrrhiza, sugar, chloroform, oil of peppermint, alcohol, and water. It is used as an expectorant.

The *dose* is two fluidrachms (8 mils).

MISTURA OLEO-BALSAMICA. N. F.

Oleo-Balsamic Mixture [Mist. Ol.-Balsam.]

This preparation contains 0.4 per cent. each of the oils of lavender, thyme, lemon, nutmeg, and cinnamon, with eugenol, balsam of Peru, and alcohol. Its greatest value lies in its pleasant odor.

MISTURA OPII ET CHLOROFORMI COMPOSITA. N. F.

Compound Mixture of Opium and Chloroform [Mist. Opii et Chlorof. Co. Squibb's Diarrhea Mixture]

This preparation contains 20 per cent. each of tincture of opium and spirit of camphor,

with tincture of capsicum, chloroform and alcohol. It is used in serous *diarrheas.*

The *dose* is thirty minims (2 mils).

MISTURA OPII ET RHEI COMPOSITA.

Compound Mixture of Opium and Rhubarb [Mist. Opii et Rhei Co. Sun Cholera Mixture]

This preparation contains 10 per cent., each, of tincture of capsicum and tincture of rhubarb, and 20 per cent., each, of tincture of opium, spirit of camphor, and spirit of peppermint, dissolved in alcohol. It is used in *cholera morbus.*

The *dose* is thirty minims (2 mils).

MISTURA OPII ET SASSAFRAS. N. F. Mistura Sassafras et Opii, N. F. III

Mixture of Opium and Sassafras [Mist. Opii et Sassaf. Mistura Opii Alkalina. Godfrey's Cordial]

This preparation contains about 2 minims of tincture of opium in 1 fluidrachm of the finished mixture together with potassium carbonate, flavored with oil of sassafras. It is intended as a preparation for exhibiting opium in children.

The *dose* for an infant is five minims (0.3 mil).

MISTURA PECTORALIS, STOKES. N. F.

Stokes' Expectorant [Mist. Pect. Stokes]

Each fluidrachm of this preparation represents, approximately, 1 grain of ammonium carbonate, 2 minims each of fluidextracts of squill and senega, and 10 minims of paregoric dissolved in water and syrup of tolu. It is used as an expectorant.

The *dose* is one fluidrachm (4 mils).

MISTURA RHEI ALKALINA. N. F. Syrupus Rhei et Potassii Compositus, N. F. III

Alkaline Mixture of Rhubarb [Mist. Rhei Alk. Neutralizing Cordial]

This preparation contains fluidextracts of rhubarb and hydrastis, potassium carbonate, tincture of cinnamon, spirit of peppermint, syrup, and diluted alcohol. It is used as a laxative, antacid and carminative for infants.

The *dose* is one fluidrachm (4 mils).

MISTURA RHEI COMPOSITA. N. F. (U. S. P. VIII) Mistura Rhei et Sodæ, U. S. P. VIII

Compound Mixture of Rhubarb [Mist. Rhei Co. Mixture of Rhubarb and Soda]

This preparation is made from the fluidextracts of rhubarb and ipecac, sodium bicarbonate, glycerin, and peppermint water. The formula is the same as that of the U. S. P. VIII. It is used as a laxative for infants. Each fluidrachm represents 0.9 grain of rhubarb.

The *dose* is one fluidrachm (4 mils).

MUCILAGO CHONDRI. N. F.

Mucilage of Chondrus [Mucil. Chondr. Mucilage of Irish Moss]

This preparation contains 3 per cent. of Irish moss in water. It is used as an emulsifying agent and demulcent.

MUCILAGO SASSAFRAS MEDULLÆ. N. F. (U. S. P. VIII)

Mucilage of Sassafras Pith [Mucil. Sassaf. Medul.]

This preparation contains 2 grammes of sassafras pith in each 100 mils. The formula is the same as that of the U. S. P. VIII. It is a bland mucilage used principally in eye lotions and should always be freshly prepared.

The *dose* is four fluidrachms (15 mils).

MULLÆ. N. F.

Mulls [Salve Mulls. Steatins]

The mulls or salve mulls are very stiff ointments spread upon soft muslin (mull) similar to a plaster. The base is usually suet or lard, but wax or even lead plaster are used in some of the members of the group.

MULLA ACIDI SALICYLICI. N. F. Unguentum Salicylatum Extensum, N. F. III

Salicylic Acid Mull [Mull. Ac. Salicyl.]

This preparation contains 10 per cent. of salicylic acid with a mixture of benzoinated suet and benzoinated lard.

MULLA CREOSOTI SALICYLATA. N. F. Unguentum Creosoti Salicylatum Extensum, N. F. III

Salicylated Creosote Mull [Mull. Creosot. Salicyl.]

This preparation contains 10 per cent. of salicylic acid and 20 per cent. of creosote in a mixture of benzoinated suet and yellow wax.

MULLA HYDRARGYRI CHLORIDI CORROSIVI. N. F. Unguentum Hydrargyri Chloridi Corrosivi Extensum, N. F. III

Corrosive Mercuric Chloride Mull [Mull. Hydrarg. Chlor. Corros.]

This preparation contains 0.2 per cent. of corrosive sublimate in a mixture of benzoinated suet, benzoinated lard, and alcohol.

MULLA ZINCI. N. F. Unguentum Zinci Extensum, N. F. III

Zinc Mull [Mull. Zinc.]

This preparation is made with zinc oxide, 10 per cent., in a mixture of benzoinated suet and benzoinated lard.

NEBULA AROMATICA. N. F.

Aromatic Oil Spray [Nebul. Arom. Aromatol]

This preparation contains phenol, menthol, thymol, camphor, benzoic acid, eucalyptol, oil of cinnamon, oil of clove and methyl salicylate in small proportions, in solution in light liquid petrolatum. It is used as an inhalant in the form of a nebula or spray. Its virtues are due chiefly to the liquid petrolatum.

NEBULA EUCALYPTOLIS. N. F.

Eucalyptol Spray [Nebul. Eucalyptol.]

This preparation contains 5 per cent. of eucalyptol in solution in light liquid petrolatum. It is used as an inhalant in the form of a nebula or spray.

NEBULA MENTHOLIS. N. F.

Menthol Spray [Nebul. Menthol.]

This preparation consists of a solution of 2 per cent. of menthol in light liquid petrolatum. It is used as an inhalant in the form of a nebula or spray.

NEBULA MENTHOLIS COMPOSITA. N. F.

Compound Menthol Spray [Nebul. Menthol. Co.]

This preparation contains 1 per cent. each of menthol and camphor, with smaller amounts of methyl salicylate, eucalyptol, and oil of cinnamon in solution in light liquid petrolatum. It is used as an inhalant in the form of a nebula or spray.

NEBULA THYMOLIS. N. F.

Thymol Spray [Nebul. Thymol.]

This preparation contains 1 per cent. of thymol in solution in light liquid petrolatum. It is used as an inhalant in the form of a nebula or spray.

OLEA INFUSA. N. F.

Infused Oils [Ol. Inf.]

The formula for these is a general one. The infused oils are made from the air dried drug, 10 per cent. with alcohol, ammonia water, and sesame oil.

OLEATUM ACONITINÆ. N. F.

Oleate of Aconitine [Oleat. Aconitin.]

This preparation is a solution of 2 per cent. of aconitine in equal parts of oleic acid and olive oil. This preparation does not deserve recognition; the danger of poisoning by it far outweighs any probability of benefit.

OLEATUM ATROPINÆ. N. F. (U. S. P. VIII)

Oleate of Atropine [Oleat. Atrop.]

This preparation is a solution of 2 per cent. of atropine in a little alcohol and equal parts of oleic acid and olive oil. The formula is the same as that of the U. S. P. VIII.

OLEATUM COCAINÆ. N. F. (U. S. P. VIII)

Oleate of Cocaine [Oleat. Cocain.]

This preparation contains 5 per cent. cocaine dissolved in a little alcohol and then incorporated with oleic acid and olive oil. The formula is the same as that of the U. S. P. VIII. It is used as a local anesthetic.

OLEATUM QUININÆ. N. F. (U. S. P. VIII)

Oleate of Quinine [Oleat. Quin.]

This preparation contains 25 per cent. of quinine in oleic acid and is used as a local anesthetic. The formula is the same as that of the U. S. P. VIII.

OLEATUM VERATRINÆ. N. F. (U. S. P. VIII)

Oleate of Veratrine [Oleat. Veratrin.]

This preparation contains 2 per cent. of veratrine in equal parts of olive oil and oleic acid, and is used as an anodyne and rubefacient. It should be used cautiously on account of the danger of systemic poisoning. The formula is the same as that of the U. S. P. VIII.

OLEORESINA LUPULINI N. F. (U. S. P. VIII)

Oleoresin of Lupulin [Oleores. Lupulin.]

Prepared in the usual method from lupulin, using ether to exhaust the drug. The U. S. P. VIII directed the use of acetone as the menstruum.

The *dose* is three grains (0.2 mil).

OLEOSACCHARA. N. F.

Oil-sugars [Elæosacchara]

These new preparations are prepared by triturating any prescribed oil (2 per cent.) with sugar. Used as adjuvants or vehicles.

OLEUM ÆTHEREUM. N. F. (U. S. P. VIII)

Ethereal Oil [Ol. Æther.]

This is a volatile liquid consisting of equal volumes of ether and of heavy oil of wine, prepared by distillation of alcohol with sulphuric acid. The process is the same as that of the U. S. P. VIII. It is transparent, nearly colorless, has a specific gravity of 0.905 at 25° C. (77° F.), a peculiar aromatic odor, and a pungent taste. Preserve in small glass-stoppered bottles in a cool place. It is used in the preparation of compound spirit of ether (Hoffmann's anodyne).

OLEUM HYOSCYAMI COMPOSITUM. N. F.

Compound Oil of Hyoscyamus [Ol. Hyosc. Co. Balsamum Tranquillans]

This preparation is made from 0.2 per cent. of the oils of lavender, peppermint, rosemary, and thyme, with infused oil of hyoscyamus. It is used as an anodyne.

OLEUM PHENOLATUM. N. F.

Oleum Carbolatum, N. F. III. Phenolated Oil [Ol. Phenol. Carbolized Oil.]

It is made by dissolving 5 per cent. of phenol in cottonseed oil. Used externally.

OLEUM PHOSPHORATUM. N. F.

Phosphorated Oil [Ol. Phosphorat.]

This preparation is made by dissolving 1 per cent. of phosphorus in 50 times its weight of expressed oil of almond with the aid of water bath heat and adding to this solution an equal volume of ether. It is a clear, yellowish liquid, having the odor of phosphorus and of ether, and free from undissolved particles. It affords an excellent means of administering phosphorus.

The *dose* is one minim (0.05 mil).

OLEUM RICINI AROMATICUM. N. F.

Aromatic Castor Oil [Ol. Ricin. Arom.]

This is castor oil flavored with benzosulphinide (0.05 per cent.), oils of clove and cinnamon, vanillin, coumarin, and alcohol.

The *dose* is four fluidrachms (15 mils).

OXYMEL SCILLÆ. N. F.

Oxymel of Squill [Oxymel Scill.]

This preparation is made from 1 part of vinegar of squill and 2 parts of clarified honey. Used as an expectorant.

The *dose* is one fluidrachm (4 mils).

PASTÆ DERMATOLOGICÆ. N. F.

Dermatologic Pastes

These preparations are ointment-like mixtures of starch, dextrin, zinc oxide, sulphur, calcium carbonate, or other medicinal substances made into a paste with glycerin, soft soap, petrolatum, etc., medicated with antiseptic or astringent agents and used in the practice of dermatologists.

PASTA BETANAPHTHOLIS. N. F. Pasta Naphtholis Lassar, N. F. III

Betanaphthol Paste [Past. Betanaphthol. Lassar's Naphthol Paste]

This preparation contains 10 per cent. of betanaphthol, 50 per cent. of sulphur, 20 per cent. of petrolatum, and 20 per cent. of soft soap. It is used externally as an antiseptic and parasiticide.

PASTA DEXTRINATA. N. F.

Dextrinated Paste [Past. Dextrin.]

This preparation contains 33 per cent. white dextrin, 33 per cent. glycerin and water. It is used as a vehicle.

PASTA RESORCINOLIS FORTIS. N. F.

Strong Resorcinol Paste [Past. Resorcin. Fort. Lassar's Stronger Resorcinol Paste]

This preparation contains 20 per cent. of resorcinol, zinc oxide, and starch, together with 40 per cent. of light liquid petrolatum. Used externally in skin diseases.

PASTA RESORCINOLIS MITIS. N. F. Pasta Resorcini Mitis, Lassar, N. F. III

Mild Resorcinol Paste [Past. Resorcin. Mit. Lassar's Mild Resorcinol Paste]

This preparation contains 10 per cent. of resorcinol with 25 per cent. each of zinc oxide and starch, and 40 per cent. of light liquid petrolatum. Used locally in diseases of the skin.

PASTA ZINCI. N. F. Pasta Zinci Lassar, N. F. III

Zinc Paste [Past. Zinc. Lassar's Zinc Paste]

This preparation contains 2 per cent. of salicylic acid, 24 per cent. of zinc oxide and starch, and 50 per cent. of petrolatum. Used as an antiseptic and protective in skin diseases.

PASTA ZINCI MOLLIS. N. F. Pasta Zinci Mollis, Unna, N. F. III

Soft Zinc Paste [Past. Zinc Moll. Unna's Soft Zinc Paste]

This preparation contains 25 per cent. each of zinc oxide, precipitated calcium carbonate,

linseed oil, and solution of calcium hydroxide (lime water). It is used as an astringent.

PASTA ZINCI SULPHURATO. N. F. Pasta Zinci Sulphurata, Unna, N. F. III

Sulphurated Zinc Paste [Past. Zinc. Sulphur. Unna's Sulphurated Zinc Paste]

This preparation contains 15 per cent. of zinc oxide, 10 per cent. of precipitated sulphur, 5 per cent. of purified siliceous earth, and 70 per cent. of benzoinated lard. It is used as an antizymotic and protective.

PEPSINUM SACCHARATUM. N. F.

Saccharated Pepsin [Pepsin. Sacchar.]

This preparation is a 10 per cent. triturate of pepsin with sugar of milk, used as a digestive.

The *dose* is fifteen grains (1 Gm.).

PETROXOLINUM BETANAPHTHOLIS. N. F.

Betanaphthol Petroxolin [Petrox. Betanaphthol. Betanaphthol Petrox]

This preparation is a 10 per cent. fresh solution of betanaphthol in liquid petroxolin. It is used as an antizymotic and parasiticide.

PETROXOLINUM CADINUM. N. F.

Cade Petroxolin [Petrox. Cadin. Cade Petrox]

This preparation is a 25 per cent. mixture of oil of cade and liquid petroxolin. It is used as an antiseptic and antiparasitic.

PETROXOLINUM CHLOROFORMI CAMPHORATUM. N. F.

Camphorated Chloroform Petroxolin [Petrox. Chlorof. Camph. Camphor and Chloroform Petrox]

This preparation is a solution of 25 per cent. each of chloroform and camphor in liquid petroxolin. It is used as an anodyne and rubefacient.

PETROXOLINUM CREOSOTI. N. F.

Creosote Petroxolin [Petrox. Creosot. Creosote Petrox]

This preparation is a mixture of creosote 20 per cent., and olive oil 5 per cent., in liquid petroxolin. It is used as an antiputrescent and antiseptic.

PETROXOLINUM EUCALYPTOLIS. N. F.

Eucalyptol Petroxolin [Petrox. Eucalyptol. Eucalyptol Petrox]

This preparation is a 20 per cent. solution of eucalyptol in liquid petroxolin. It is used as an antiseptic and rubefacient.

PETROXOLINUM GUAIACOLIS. N. F.

Guaiacol Petroxolin [Petrox. Guaiacol. Guaiacol Petrox]

This preparation is a mixture of guaiacol 20 per cent., olive oil 5 per cent., and liquid petroxolin. It is used externally as a deodorant and antipyretic.

PETROXOLINUM HYDRARGYRI. N. F.

Mercury Petroxolin [Petrox. Hydrarg. Mercury Petrox]

This preparation contains 30 per cent. of mercury extinguished with 13 per cent. of hydrous wool fat and 2 per cent. oleic acid and solid petroxolin added. It is used as an antisyphilitic and antiparasitic.

PETROXOLINUM IODI. N. F.

Iodine Petroxolin [Petrox. Iod. Iodine Petrox, 10 per cent.]

This preparation is a mixture of 10 per cent. iodine, 40 per cent. oleic acid, 20 per cent. alcohol, 23 per cent. light liquid petrolatum, 2 per cent. oil of lavender, and 5 per cent. stronger ammonia water. It is used as a counter irritant and discutient.

PETROXOLINUM IODI DILUTUM. N. F.

Diluted Iodine Petroxolin [Petrox. Iod. Dil. Iodine Petrox, 5 per cent.]

This preparation is a solution of 5 per cent. iodine in liquid petroxolin. It is used as an absorbent and discutient.

PETROXOLINUM IODOFORMI. N. F.

Iodoform Petroxolin [Petrox. Iodoform. Iodoform Petrox]

This preparation is a freshly prepared solution of 3 per cent. iodoform, 20 per cent. acetone, 10 per cent. oleic acid, 3 per cent. eucalyptol, and liquid petroxolin. It is used as an antitubercular and antiseptic.

PETROXOLINUM LIQUIDUM. N. F. Petrolatum Saponatum Liquidum, N. F. III

Liquid Petroxolin [Petrox. Liq. Liquid Petrox]

This preparation is made from 50 per cent. light liquid petrolatum, 28 per cent. oleic acid, 2 per cent. oil of lavender, 5 per cent. stronger ammonia water, and 15 per cent. alcohol. It is a yellowish-brown liquid, miscible with ether, chloroform, petroleum benzin or acetone and producing an emulsion-like mixture when added to twice its volume of water. It is used as a vehicle.

PETROXOLINUM MENTHOLIS. N. F.

Menthol Petroxolin [Petrox. Menthol. Menthol Petrox]

This preparation is a solution of menthol, 17 per cent., in liquid petroxolin. It is used as a local anesthetic.

PETROXOLINUM METHYLIS SALICYLATIS. N. F.

Methyl Salicylate Petroxolin [Petrox. Methyl. Sal. Methyl Salicylate Petrox]

This preparation is a solution of methyl salicylate, 20 per cent., in liquid petroxolin. It is used as an antirheumatic.

PETROXOLINUM PHENOLIS. N. F.

Phenol Petroxolin [Petrox. Phenol. Phenol Petrox]

This preparation is a 5 per cent. solution of phenol in liquid petroxolin. It is used as an antiseptic and local anesthetic.

PETROXOLINUM PHENOLIS CAMPHORATUM. N. F.

Camphorated Phenol Petroxolin [Petrox. Phenol. Camph. Camphorated Phenol Petrox]

This contains 12.5 per cent. phenol and 37.5 per cent. camphor in liquid petroxolin. It is used as an analgesic.

PETROXOLINUM PICIS. N. F.

Tar Petroxolin [Petrox. Pic. Tar Petrox]

This preparation is a mixture of 25 per cent. rectified oil of tar in liquid petroxolin. It is used as a deodorant and parasiticide.

PETROXOLINUM SPISSUM. N. F. Petrolatum Saponatum Spissum, N. F. III

Solid Petroxolin [Petrox. Spiss. Solid Petrox]

This preparation is a mixture of 35 per cent. white wax, 20 per cent. light liquid petrolatum, 32 per cent. oleic acid, 3 per cent. oil of lavender, 5 per cent. alcohol, and 5 per cent. stronger ammonia water. It is used as a vehicle for ointments.

PETROXOLINUM SULPHURATUM. N. F.

Sulphurated Petroxolin [Petrox. Sulphur. Sulphurated Petrox]

This preparation is a mixture of 3 per cent. sublimed sulphur, 37 per cent. linseed oil, 30 per cent. oleic acid, and liquid petroxolin. It is used as a parasiticide.

PETROXOLINUM SULPHURATUM COMPOSITUM. N. F.

Compound Sulphurated Petroxolin [Petrox. Sulphur. Co. Compound Sulphurated Petrox.

This preparation is made from 10 per cent. sulphurated petroxolin, 10 per cent. oil of cade, 0.3 per cent. thymol, 3 per cent. eucalyptol, 30 per cent. oil of turpentine, and liquid petroxolin. It is used as a parasiticide.

PETROXOLINUM TEREBINTHINÆ LARICIS. N. F.

Venice Turpentine Petroxolin [Petrox. Terebinth. Laric. Venice Turpentine Petrox]

This preparation is a solution of 20 per cent. Venice turpentine in liquid petroxolin. It is used as a vulnerary rubefacient in veterinary practice.

PHENOL IODATUM. N. F. Acidum Carbolicum Iodatum, N. F. III

Iodized Phenol [Phenol. Iodat.]

This is made from iodine 20 per cent., phenol 60 per cent., and glycerin. It is an active germicide.

PILULÆ. N. F.

Pills

Pills are globular or ovoid dosage forms of medicinal substances intended for internal administration. Each pill weighs not less than 0.06 Gm., nor more than 0.5 Gm. If they weigh less than 0.06 Gm. and more than 0.02 Gm. each they are known as *"Granules"*; if the weight is less than 0.02 Gm., they are usually designated as *"Parvules."* The ingredients are massed by the aid of selected excipients.

For the extemporaneous coating of pills by the pharmacist, formulas and working directions for the following methods are supplied: gelatin, sugar, cocoa, tolu, silver, and salol coatings. For the coating of the so-called "enteric pills," the use of salol is recommended.

PILULÆ AD PRANDIUM. N. F.

Dinner Pills [Pil. Ad. Prand.]

When dinner pills are prescribed, the official pills of aloes and mastic should be dispensed.

Dose, of dinner pills, one or two.

Other so-called dinner pills are as follows:

Chapman's Dinner Pill.—Each pill contains

1½ grains of purified aloes, 1½ grains of mastic, 1 grain of ipecac and about ¼ minim of oil of fennel.

Cole's Dinner Pill.—Each pill contains 1 and 1-5th of a grain each of purified aloes, mass of mercury, and jalap and 1-50th of a grain of antimony and potassium tartrate.

Hall's Dinner Pill.—Each pill contains 1 grain each of purified aloes, extract of glycyrrhiza, soap, and syrup.

PILULÆ ALOES ET ASAFŒTIDÆ. N. F.

Pills of Aloes and Asafetida [Pil. Aloe. et Asafœt.]

Each pill contains 0.09 Gm. (1½ grains) each of aloes, soap, and asafetida massed with water.

The *dose* is one pill.

PILULÆ ALOES ET FERRI. N. F. (U. S. P. VIII)

Pills of Aloes and Iron [Pil. Aloe. et Ferr.]

Each pill contains about 1 grain each of aloes, exsiccated ferrous sulphate and aromatic powder massed with confection of rose. The formula is the same as that of the U. S. P. VIII.

The *dose* is two pills.

PILULÆ ALOES ET MASTICHES. N. F. (U. S. P. VIII)

Pills of Aloes and Mastic [Pil. Aloe. et Mastich. Lady Webster's Dinner Pills]

Each pill contains 2 grains of aloes, ¾ grain of mastic, and ½ grain of red rose massed with diluted alcohol. The formula is the same as that of the U. S. P. VIII.

The *dose* is two pills.

PILULÆ ALOES ET MYRRHÆ. N. F. (U. S. P. VIII)

Pills of Aloes and Myrrh [Pil. Aloe. et Myrrh.]

Each pill contains 2 grains of aloes, 1 grain of myrrh, ¾ grain of aromatic powder, massed with syrup. The formula is the same as that of the U. S. P. VIII.

The *dose* is two pills.

PILULÆ ALOES ET PODOPHYLLI COMPOSITÆ. N. F.

Compound Pills of Aloes and Podophyllum [Pil. Aloe. et Podoph. Co. Janeway's Pills]

Each pill contains 1 grain of purified aloes, ½ grain resin of podophyllum, ¼ grain of extract of belladonna leaves, and ¼ of a grain of extract of nux vomica. They are used as a laxative and hepatic tonic.

The *dose* is one pill.

PILULÆ ALOES, HYDRARGYRI ET PODOPHYLLI. N. F. Pilulæ Triplices, N. F. III

Pills of Aloes, Mercury, and Podophyllum [Pil. Aloe. Hydrarg. et Podoph. Triplex Pills. Pilula Triplex]

Each pill contains 2 grains of aloes, 1 grain mass of mercury, and ¼ grain resin of podophyllum. They are used as a cathartic and hepatic tonic.

The *dose* is one pill.

PILULÆ ALOES, HYDRARGYRI ET SCAMMONII COMPOSITÆ. N. F.

Compound Pills of Aloes, Mercury, and Scammony [Pil. Aloe. Hydrarg. et Scammon. Francis' "Triplex" Pills]

Each pill contains ⅝ grain each of aloes, resin of scammony, and mass of mercury, 1-20th minim of croton oil and ¼ minim oil of caraway. Used as a cathartic, the *dose* being one pill.

PILULÆ ALOINI COMPOSITÆ. N. F.

Compound Pills of Aloin [Pil. Aloin. Co.]

Each pill contains ½ grain of aloin, ⅛ grain of resin of podophyllum, ¼ grain of extract of belladonna leaves. Cathartic.

The *dose* is one pill.

PILULÆ ALOINI, STRYCHNINÆ ET BELLADONNÆ. N. F.

Pills of Aloin, Strychnine and Belladonna [Pil. A. S. et B.]

Each pill contains 1-5th grain of aloin, 1-120th grain of strychnine, and ⅛ grain of extract of belladonna leaves. Used as a laxative.

The *dose* is one pill.

PILULÆ ALOINI, STRYCHNINÆ ET BELLADONNÆ COMPOSITÆ. N. F.

Compound Pills of Aloin, Strychnine and Belladonna [Pil. A. S. et B. Co.]

Each pill contains 1-5th grain of aloin, 1-120th grain of strychnine, ⅛ grain of extract of belladonna leaves, and ½ grain of extract of cascara sagrada. Used as a laxative.

The *dose* is one pill.

PILULÆ ANTIDYSPEPTICÆ. N. F.

Antidyspeptic Pills [Pil. Antidyspep.]

Each pill contains 1-40th grain of strychnine, 1-10th grain of ipecac, 1-10th grain of

extract of belladonna leaves, 2 grains of mass of mercury, and 2 grains of compound extract of colocynth. Used as a cholagogue.

The *dose* is one pill.

PILULÆ ANTIMONII COMPOSITÆ. N. F.

Compound Pills of Antimony [Pil. Antimon. Co. Plummer's Pills]

Each pill contains 3-5th grain of sulphurated antimony and calomel, 1 and 1-5th grain of guaiac, and castor oil.

The dose, as an alterative and diaphoretic, is one pill.

PILULÆ ANTIPERIODICÆ. N. F.

Antiperiodic Pills [Pil. Antiperiod. Warburg's Pills]

Each pill contains 1 grain of extract of aloes, ½ grain of rhubarb, ½ grain of angelica seed, ¼ grain of elecampane, ¼ grain of saffron, ¼ grain of fennel, ⅛ grain of zeodoary root, ⅛ grain of cubebs, ⅛ grain of myrrh, ⅛ grain of white agaric, ⅛ grain of camphor, 1 and 2-5th grains of quinine sulphate, with a sufficient quantity of extract of gentian to form a mass. Used as an antiperiodic.

The *dose* is one to three pills one to three times daily.

PILULÆ ANTIPERIODICÆ SINE ALOE. N. F.

Antiperiodic Pills without Aloes [Pil. Antiperiod. s. Aloe. Warburg's Pills without Aloes]

The formula is similar to that for the preceding pill, but the extract of aloes is omitted.

The *dose* is one pill.

PILULÆ CATHARTICÆ VEGETABILES. N. F. (U. S. P. VIII)

Vegetable Cathartic Pills [Pil. Cathart. Veget.]

Each pill contains 1 grain compound extract of colocynth, ½ grain extract of hyoscyamus, ¼ grain of resin of jalap, and 1-5th grain each of extract of leptandra and resin of podophyllum with 1-10th minim oil of peppermint and massed with diluted alcohol. Used as a cathartic.

The *dose* is two pills.

PILULÆ COLOCYNTHIDIS COMPOSITÆ. N. F.

Compound Pills of Colocynth [Pil. Colocynth. Co. Pilulæ Cocciæ. Cochia Pills]

Each pill contains 1-6th grain of extract of colocynth, 2 grains of purified aloes, 2 grains of resin of scammony and ¼ minim of oil of clove. Used as a cathartic.

The *dose* is one pill.

PILULÆ COLOCYNTHIDIS ET HYOSCYAMI. N. F.

Pills of Colocynth and Hyoscyamus [Pil. Colocynth. et Hyoscy.]

Each pill contains 1-10th grain of extract of colocynth, 1½ grains of purified aloes, 1½ grains of resin of scammony, ⅛ minim of oil of clove, and 1½ grains of extract of hyoscyamus. Used as a cathartic.

The *dose* is one pill.

PILULÆ COLOCYNTHIDIS ET PODOPHYLLI. N. F.

Pills of Colocynth and Podophyllum [Pil. Colocynth. et Podoph.]

Each pill contains 2½ grains of compound extract of colocynth, and ¼ grain of resin of podophyllum. Used as a cathartic.

The *dose* is one pill.

PILULÆ DIGITALIS, SCILLÆ ET HYDRARGYRI. N. F.

Pills of Digitalis, Squill, and Mercury [Pil. Digit. Scill. et Hydrarg. Niemeyer Pills for Dropsy. Guy's Pills]

Each pill contains 1 grain each of digitalis, squill, and mercury massed with clarified honey. Used as a diuretic. They must be carefully distinguished from Niemeyer's pill for *phthisis* (see *Pilulæ Opii Digitalis et Quininæ*).

The *dose* is one pill.

PILULÆ FERRI, QUININÆ, ALOES ET NUCIS VOMICÆ. N. F. Pilulæ Quadruplices, N. F. III

Pills of Iron, Quinine, Aloes and Nux Vomica [Pil. Ferr. Quin. Aloe. et Nuc. Vom. Quadruplex Pills Pilulæ Ferri et Quininæ Compositæ]

Each pill contains 1 grain each of dried ferrous sulphate, quinine sulphate, and aloes, ¼ grain of extract of nux vomica, and enough extract of gentian to mass. Used as a tonic and hematinic.

The *dose* is one pill.

PILULÆ FERRI, QUININÆ, STRYCHNINÆ ET ARSENI FORTIORES N. F. Pilulæ Metallorum, N. F. III

Stronger Pills of Iron, Quinine, Strychnine and Arsenic [Pil. Ferr. Quin. Strych. et Arsen. Fort. Metallic Pills. Pilulæ Metallorum Amaræ. Bitter Metallic Pills]

Each pill contains 1 grain of reduced iron and quinine sulphate, and 1-20th grain of strych-

nine and arsenic trioxide massed with clarified honey. Used as a tonic.
The *dose* is one pill.

PILULÆ FERRI, QUININÆ, STRYCHNINÆ ET ARSENI MITES. N. F

Mild Pills of Iron, Quinine, Strychnine, and Arsenic [Pil. Ferr. Quin. Strych. et Arsen. Mit. Aitken Tonic Pills]

Each pill contains ⅔ grain of reduced iron and 1 grain of quinine sulphate, and 1/50 grain each of strychnine and arsenic trioxide massed with clarified honey. Used as a tonic.
The *dose* is one pill.

PILULÆ GLYCERYLIS NITRATIS. N. F.
Pilulæ Glonoini, N. F. III

Pills of Nitroglycerin [Pil. Glycer. Nit. Pills of Glonoin]

They are made from spirit of glyceryl trinitrate, althea and confection of rose. Each pill contains 1-100th grain of nitroglycerin. They offer a convenient means of exhibiting nitroglycerin, but are likely to deteriorate if not properly kept.
The *dose* is one pill.

PILULÆ LAXATIVÆ COMPOSITÆ. N. F. (U. S. P. VIII)

Compound Laxative Pills [Pil. Lax. Co.]

Each pill contains ¼ grain aloin, 1-120th grain strychnine, ⅛ grain extract of belladonna leaves, 1-16th grain of ipecac, licorice and syrup to mass. Used as a laxative.
The *dose* is two pills.

PILULÆ LAXATIVÆ POST PARTUM. N. F.

Post Partum Laxative Pills [Pil. Lax. Post Part. Barker's Post Partum Pills]

Each pill contains 1⅔ grains of compound extract of colocynth, ⅝ grain of purified aloes, 5-12th grain of extract of nux vomica, 1-12th grain of resin of podophyllum, 1-12th grain of ipecac, and 1¼ grains of extract of hyoscyamus. The formula is the same as that of the U. S. P. VIII. Used as a cathartic, the *dose* being one pill.

PILULÆ OPII, DIGITALIS ET QUININÆ. N. F.

Pills of Opium, Digitalis, and Quinine [Pil. Opii, Digit. et Quin. Niemeyer Pills for Phthisis]

Each pill contains 3-16th grain of opium and 1 grain each of digitalis and quinine. Used as diuretic and tonic.
The *dose* is one pill.

PILULÆ OPII ET CAMPHORÆ. N. F.

Pills of Opium and Camphor [Pil. Opii et Camph.]

Each pill contains 1 grain of powdered opium and 2 grains of camphor. Used in *diarrhea.*
The *dose* is one pill.

PILULÆ OPII ET PLUMBI. N. F.

Pills of Opium and Lead [Pil. Opii et Plumb.]

Each pill contains 1 grain of powdered opium and 1 grain of lead acetate. Used as an anodyne and astringent in serous *diarrheas.*
The *dose* is one pill.

PILULÆ RHEI. N. F.

Pills of Rhubarb [Pil. Rhei]

Each pill contains 3 grains of rhubarb and 1 grain of soap. Used as a laxative.
The *dose* is one pill.

POTASSA CUM CALCE. N. F.

Potassa with Lime [Pot. c. Calc.]

By triturating equal parts of burnt lime and caustic potash. Used as a caustic.

PULVIS ACETANILIDI COMPOSITUS. N. F. (U. S. P. VIII)

Compound Acetanilid Powder [Pulv. Acetan. Co.]

A mixture of acetanilid, 70 per cent., caffeine, 10 per cent., and sodium bicarbonate, 20 per cent. The formula is the same as that of the U. S. P. VIII. Used as an analgesic and antipyretic.
The *dose* is five grains (0.3 Gm.).

PULVIS ALOES ET CANELLÆ. N. F.

Powder of Aloes and Canella [Pulv. Aloe. et Canell. Hiera Picra]

It contains 80 per cent. of purified aloes and 20 per cent. of powdered canella. It is used as an emmenagogue and laxative.
The *dose* is five grains (0.3 Gm.).

PULVIS ANTIMONIALIS. N. F.

Antimonial Powder [Pulv. Antimon. James' Powder]

A mixture of antimony oxide, 33 per cent., and precipitated calcium phosphate, 67 per cent. Used as a diaphoretic.
The *dose* is three grains (0.2 Gm.).

PULVIS ANTISEPTICUS. N. F.

Soluble Antiseptic Powder [Pulv. Antisept. Pulvis Antisepticus Solubilis]

It contains salicylic acid, phenol, eucalyptol, menthol, thymol, zinc sulphate and powdered boric acid. It is used as an antiseptic.

PULVIS AROMATICUS RUBEFACIENS. N. F. Replacing Emplastrum Aromaticum, N. F. III

Rubefacient Spice Powder [Pulv. Arom. Rubefac.]

Consists of clove, 30 per cent., Saigon cinnamon, 30 per cent., ginger, 20 per cent., and capsicum, 20 per cent.

NOTE.—When rubefacient spice powder is needed for *Spice Poultice,* place the required quantity in a flat muslin bag and moisten it with either diluted alcohol or vinegar, previously heated.

PULVIS CRETÆ AROMATICUS. N. F.

Aromatic Powder of Chalk [Pulv. Cret. Arom.]

It contains 8 per cent. of cinnamon, 6 per cent. of nutmeg, 3 per cent. of clove, 2 per cent of cardamom seed, 25 per cent. of prepared chalk and 56 per cent. of sugar. It is used in *diarrhea.*

The *dose* is thirty grains (2 Gm.).

PULVIS CRETÆ ET OPII AROMATICUS. N. F. Pulvis Cretæ Aromaticus cum Opio, N. F. III

Aromatic Powder of Chalk and Opium [Pulv. Cret. et Opii Arom.]

One grain of powdered opium and 39 grains of aromatic powder of chalk are contained in 40 grains of this preparation. It is used in *cholera morbus.*

The *dose* is fifteen grains (1 Gm.).

PULVIS GAMBIR COMPOSITUS. N. F. Pulvis Catechu Compositus, N. F. III

Compound Powder of Gambir [Pulv. Gambir Co.]

Contains gambir, 40 per cent., kino and krameria, each, 20 per cent., and cinnamon and nutmeg, of each, 10 per cent. Used as an intestinal astringent.

The *dose* is twenty grains (1.3 Gm.).

PULVIS HYDRARGYRI CHLORIDI MITIS ET JALAPÆ. N. F.

Powder of Mild Mercurous Chloride and Jalap [Pulv. Hydrarg. Chlor. Mit. et Jalap. Calomel and Jalap]

It contains 34 per cent. of mild chloride of mercury and 66 per cent. of jalap. It is cathartic and cholagogue.

The *dose* is ten grains (0.65 Gm.).

PULVIS KINO ET OPII COMPOSITUS. N. F. Pulvis Kino Compositus, N. F. III

Compound Powder of Kino and Opium [Pulv. Kino et Opii Co.]

It contains 75 per cent. of powdered kino, 5 per cent. of powdered opium and 20 per cent. of powdered Saigon cinnamon. Used as an astringent.

The *dose* is fifteen grains (1 Gm.).

PULVIS MYRICÆ COMPOSITUS. N. F.

Compound Powder of Bayberry [Pulv. Myric. Co. Composition Powder]

It contains 60 per cent. of bayberry bark, 30 per cent. of ginger, 5 per cent. of capsicum, and 5 per cent. of clove. It is used as a carminative and stimulant.

The *dose* is fifteen grains (1 Gm.).

PULVIS PANCREATINI COMPOSITUS. N. F. Pulvis Pancreaticus Compositus, N. F. III

Compound Pancreatin Powder [Pulv. Pancreat. Co. Peptonizing Powder]

It contains 20 per cent. of pancreatin and 80 per cent. of sodium bicarbonate. Twenty-five grains of this powder are sufficient to peptonize 1 pint of fresh cow's milk. Used for preparing "predigested" foods.

PULVIS RHEI ET MAGNESIÆ ANISATUS. N. F.

Anisated Powder of Rhubarb and Magnesia [Pulv. Rhei et Magnes. Anis. Compound Anise Powder]

It contains 35 per cent. of powdered rhubarb and 65 per cent. of heavy magnesia, with anethol and alcohol. It is laxative and carminative.

The *dose* for infants is five grains (0.3 Gm.).

PULVIS TALCI COMPOSITUS. N. F. Pulvis Talci Salicylicus, N. F. III

Compound Powder of Talc [Pulv. Talc. Co. Boro-Salicylated Powder of Talc]

It contains 3 per cent. of salicylic acid, 10 per cent. of boric acid, and 87 per cent. of talc,

all in very fine powder. Used as an antiseptic dusting powder.

SALIA EFFERVESCENTIA. N. F.

Granular Effervescent Salts

Two general processes are given for preparing effervescent salts, the one to be used being determined by the quantity of material taken. The products, however, from both processes should be identical. The granulation is performed in an oven or on a water bath. The dry granular powder is passed through a No. 6 tinned-iron sieve, and immediately transferred to dry bottles or containers, and hermetically sealed.

SAL CAROLINUM FACTITIUM. N. F.

Artificial Carlsbad Salt [Sal. Carol. Fact.]

1. *In a Dry, Amorphous Form* (*G. P.*).—It contains 2 per cent. of potassium sulphate, 18 per cent. of sodium chloride, 36 per cent. of sodium bicarbonate, and sodium sulphate to make about 100 parts. Sixteen grains of this salt when dissolved in 6½ fluidounces of water represent an equal volume of Carlsbad water (Sprudel). Used as a laxative.

2. *In a Crystalline Form.*—It is made from 2 parts of potassium sulphate, 18 parts of sodium chloride, 28 parts of monohydrated sodium carbonate, 100 parts of crystallized sodium sulphate, and 100 parts of distilled water. Twenty-seven grains of this salt dissolved in 6½ fluidounces of water represent an equal volume of Carlsbad water (Sprudel). It is a laxative.

SAL CAROLINUM FACTITIUM EFFERVESCENS. N. F.

Pulvis Salis Carolini Factitii Effervescens, N. F. III. Effervescent Artificial Carlsbad Salt [Sal. Carol. Fact. Eff.]

It contains artificial Carlsbad salt, sodium bicarbonate, tartaric acid, and citric acid. Ninety grains of this powder dissolved in 6½ fluidounces of water represent an equal volume of Carlsbad water (Sprudel). Used as a laxative.

The *dose* is ninety grains (6 Gm.).

SAL KISSINGENSE FACTITIUM. N. F.

Artificial Kissingen Salt [Sal Kissingen. Fact.]

It is made from 1.7 parts of potassium chloride, 35.7 parts of sodium chloride, 12 parts of magnesium sulphate and 10.7 parts of sodium bicarbonate. Twenty-four grains of this salt dissolved in 6½ fluidounces of water represents an equal volume of Kissingen water (Rakoczi). It is an antacid laxative.

SAL KISSINGENSE FACTITIUM EFFERVESCENS. N. F. Pulvis Salis Kissingensis Factitii Effervescens, N. F. III

Effervescent Artificial Kissingen Salt [Sal Kissingen. Fact. Eff.]

It contains artificial Kissingen salt, sodium bicarbonate, tartaric acid, and citric acid. Eighty-five grains of this powder dissolved in 6½ fluidounces of water represent an equal volume of Kissingen water (Rakoczi). It is an antacid laxative.

The *dose* is eighty grains (5.5 Gm.).

SAL LITHII CITRATIS EFFERVESCENS. N. F.

Effervescent Salt of Lithium Citrate. Lithii Citras Effervescens (U. S. P. VIII), Effervescent Lithium Citrate [Sal. Lith. Cit. Eff.]

This preparation contains 5 per cent. lithium citrate, and is prepared according to the general formula. It is used as an antilithic and diuretic.

The *dose* is one hundred and twenty grains (8 Gm.).

SAL POTASSII BROMIDI EFFERVESCENS. N. F. Pulvis Potassii Bromide Effervescens, N. F. III

Effervescent Salt of Potassium Bromide [Sal Pot. Brom. Eff.]

This preparation contains 16.6 per cent. of potassium bromide. Used as a nerve sedative.

The *dose* is ninety grains (6 Gm.).

SAL POTASSII BROMIDI EFFERVESCENS COMPOSITUM. N. F. Pulvis Potassii Bromidi Effervescens cum Caffeina, N. F. III

Compound Effervescent Salt of Potassium Bromide [Sal Pot. Brom. Eff. Co. Effervescent Potassium Bromide with Caffeine]

This preparation contains 0.8 per cent. caffeine, 8.3 per cent. potassium bromide, and 4.2 per cent. lithium carbonate. Used as a nerve sedative.

The *dose* is ninety grains (6 Gm.).

SAL VICHYANUM FACTITIUM. N. F.

Artificial Vichy Salt [Sal Vichy. Fact.]

It contains sodium bicarbonate, potassium carbonate, magnesium sulphate (anhydrous), and sodium chloride. Sixteen grains dissolved

in 6½ fluidounces of water represents an equal volume of Vichy water (Grande Grille). It is antacid and mildly laxative.

SAL VICHYANUM FACTITIUM EFFERVESCENS. N. F. Pulvis Salis Vichyani Factitii Effervescens, N. F. III

Effervescent Artificial Vichy Salt [Sal Vichy. Fact. Eff.]

It contains artificial Vichy salt, sodium bicarbonate, tartaric acid, and citric acid. Fifty-seven grains of this powder dissolved in 6½ fluidounces of water represents an equal volume of Vichy water (Grande Grille). It is an antacid.

The *dose* is sixty grains (4 Gm.).

SAL VICHYANUM FACTITIUM EFFERVESCENS CUM LITHIO. N. F. Pulvis Salis Vichyani Factitii Effervescens cum Lithio, N. F. III

Effervescent Artificial Vichy Salt with Lithium [Sal Vichy. Fact. Eff. c. Lith.]

It contains artificial Vichy salt, lithium citrate, sodium bicarbonate, tartaric acid, and citric acid. Ninety grains of this powder represent about 22 grains of artificial Vichy salt and 7½ grains of lithium citrate. It is antacid and antilithic.

The *dose* is ninety grains (6 Gm.).

SEVUM BENZOINATUM. N. F.

Benzoinated Suet [Sev. Benz.]

Prepared by digesting suet with 3 per cent. of powdered benzoin. It is used as an ointment vehicle (see p. 1006).

SODA CUM CALCE. N. F.

Soda with Lime [Sod. c. Calc. London Paste]

It is made from equal parts of sodium hydroxide and lime. Used as a caustic externally.

SODII BORO-BENZOAS N. F.

Sodium Boro-Benzoate [Sod. Boro-Benz.]

It is made from 3 parts of sodium borate and 4 parts of sodium benzoate. Used as an antiseptic, and in urinary affections.

The *dose* is thirty grains (2 Gm.).

SPECIES EMOLLIENTES. N. F.

Emollient Species [Spec. Emoll. Emollient Cataplasm]

It is made from equal parts of althæa leaves, mallow leaves, melilot tops, matricaria, and flaxseed. Emollient; used for making an emollient poultice, by adding to it a suitable quantity of hot water.

SPECIES LAXATIVÆ. N. F. Species Laxantes, N. F. III

Laxative Species [Spec. Lax. St. Germain Tea]

It contains 40 per cent. of cut senna, 25 per cent. of elder flowers, 12.5 per cent. of bruised fennel, 12.5 per cent. of bruised anise, and 10 per cent. of potassium bitartrate. Used as a laxative.

The *dose* is twenty grains (1.3 Gm.).

SPECIES PECTORALES. N. F.

Pectoral Species [Spec. Pect. Species ad Infusum Pectorale. Breast Tea]

It contains 8 parts of althæa, peeled, 4 parts of coltsfoot leaves, 3 parts of Russian glycyrrhiza, peeled, 2 parts of anise, 2 parts of mullein flowers, and 1 part of orris root. Used as a pectoral.

The *dose* is one drachm (4 Gm.).

SPIRITUS ACIDI FORMICI. N. F.

Spirit of Formic Acid [Sp. Ac. Formic. Spiritus Formicarum. Spirit of Ants]

It contains 4 per cent. of formic acid in alcohol and distilled water. Used externally as a counter-irritant, and internally as a diuretic.

The *dose* is one fluidrachm (4 mils).

SPIRITUS ÆTHERIS COMPOSITUS. N. F. (U. S. P. VIII)

Compound Spirit of Ether [Sp. Æth. Co. Hoffmann's Anodyne]

This preparation contains 2.5 per cent. ethereal oil in a solution of ether in alcohol (1 : 2). The formula is the same as that of the U. S. P. VIII. Used as a stimulant and antispasmodic.

The *dose* is one fluidrachm (4 mils).

SPIRITUS AMMONIÆ ANISATUS. N. F.

Anisated Spirit of Ammonia [Sp. Ammon. Anis. Liquor Ammoniæ Anisatus. Anisated Solution of Ammonia]

This preparation is a solution of anethol, 3 per cent., in a mixture of 20 per cent. ammonia water in alcohol. Used as a carminative and restorative.

The *dose* is fifteen minims (1 mil).

SPIRITUS CARDAMOMI COMPOSITUS. N. F.

Compound Spirit of Cardamom [Sp. Card. Co.]

It is made from the oils of cardamom, orange, cinnamon, clove, and caraway, and anethol dissolved in alcohol. Used for flavoring, being equivalent to compound tincture of cardamom, without the coloring matter.

SPIRITUS MYRCIÆ COMPOSITUS. N. F.

Spiritus Myrciæ, N. F. III
Compound Spirit of Myrcia [Sp. Myrciæ Co.]

A hydroalcoholic solution of oils of bay, orange, and allspice. It is commonly called *Bay Rum.*

SPIRITUS ODORATUS. N. F.

Perfumed Spirit [Sp. Odorat.]

A hydroalcoholic solution of oil of bergamot, lemon, rosemary, lavender, orange flowers, and acetic ether. Used as a perfume under the title *cologne water.*

SPIRITUS OLEORUM VOLATILIUM. N. F.

Spirits of Volatile Oils

Any spirit of a volatile oil for which no specific formula is provided may be prepared by dissolving 6.5 parts of the oil in 93.5 parts of alcohol.

SPIRITUS SINAPIS. N. F.

Spirit of Mustard [Sp. Sinap.]

This spirit contains 2 per cent. of volatile oil of mustard in alcohol. Used as a counter-irritant.

SPIRITUS VANILLINI COMPOSITUS. N. F.

Compound Spirit of Vanillin [Sp. Vanil. Co.]

This preparation contains vanillin, 20 per cent., oil of orange, 5 per cent., oil of cardamom, 1 per cent., and oil of cinnamon, 0.5 per cent., in alcohol. Used as a flavoring agent.

STILI DILUBILES N. F.

Paste Pencils [Stil. Dilub. Unna Pencils]

These are preparations in the form of a pencil, the medicinal agent incorporated in a paste made from starch, dextrin, tragacanth, sugar, and water. They are rolled into cylinders 5 mm. thick and 5 cm. long. They are used in dermatological practice. The N. F. gives one formula as exemplar (see succeeding article).

STILI ACIDI SALICYLICI DILUBILES. N. F.

Stilus Acidi Salicylici Dilubilis, N. F. III
Salicylic Acid Pencil [Stil. Acid. Salicyl. Dilub.]

These pencils contain 10 per cent. of salicylic acid, with tragacanth, starch, dextrin, sugar, and distilled water.

SUCCUS CITRI ET PEPSINUM. N. F.

Succus Limettæ cum Pepsino, N. F. III
Lime Juice and Pepsin [Suc. Cit. et Pepsin.]

It is made from 40 per cent. of glycerite of pepsin, and 60 per cent. of lime juice. Used in *dyspepsia.*

The *dose* is two fluidrachms (8 mils).

SULPHURIS IODIDUM. N. F. (U. S. P. VIII)

Sulphur Iodide [Sulphur. Iod.]

Prepared by fusing together 20 Gm. washed sulphur and 80 Gm. of iodine. The formula is the same as that of the U. S. P. VIII. It occurs in brittle masses having a crystalline fracture and a grayish-black, metallic luster. Almost insoluble in water; soluble in about 60 parts of glycerin; very soluble in carbon disulphide. Alcohol, ether, or an aqueous solution of potassium iodide dissolves the iodine, leaving the sulphur. Continued boiling with water vaporizes all of the iodine, leaving about 20 per cent. of sulphur as a residue. It is used as an antiparasitic.

SUPPOSITORIA BOROGLYCERINI. N. F.

Suppositories of Boroglycerin [Suppos. Boroglycer.]

The suppositories contain glycerinated gelatin, glycerin, and glycerite of boroglycerin, 30 per cent.

SYRUPUS ALLII. N. F.

Syrup of Garlic [Syr. Allii]

Prepared from garlic (20 per cent.), sugar, and diluted acetic acid. Used as an expectorant and diuretic.

The *dose* is one fluidrachm (4 mils).

SYRUPUS ALTHÆÆ. N. F.

Syrup of Althæa [Syr. Althæ.]

Prepared from althæa (5 per cent.), and contains 10 per cent. of glycerin. Used as a demulcent vehicle.

Keep the syrup in well-stoppered, completely filled bottles, in a cool place.

The *dose* is one fluidrachm (4 mils).

SYRUPUS AMMONII HYPOPHOSPHITIS. N. F.

Syrup of Ammonium Hypophosphite [Syr. Ammon. Hypophos.]

One fluidrachm (4 mils) of this syrup contains two grains (0.125 Gm.) of ammonium hypophosphite. It is flavored with compound spirit of vanillin. Used as a tonic.

The *dose* is one fluidrachm (4 mils).

SYRUPUS ASARI COMPOSITUS. N. F.

Compound Syrup of Asarum [Syr. Asar. Co.]

It is made from asarum root, alcohol, cochineal, potassium carbonate, fluidextract of ipecac, sugar, and water. About 3.5 grains of asarum and one-sixth grain of ipecac are represented by 1 fluidrachm of finished syrup.

The *dose* is one fluidrachm (4 mils).

SYRUPUS BROMIDORUM. N. F.

Syrup of the Bromides [Syr. Bromidor.]

It is made from potassium, sodium, ammonium, calcium, and lithium bromides, tincture of vanilla, compound tincture of cudbear, compound syrup of sarsaparilla and syrup. About 15 grains of the mixed bromides are contained in 1 fluidrachm of the finished syrup. Used as a nerve sedative.

The *dose* is one fluidrachm (4 mils).

SYRUPUS CALCII ET SODII HYPOPHOSPHITUM. N. F.

Syrup of Calcium and Sodium Hypophosphites [Syr. Calc. et Sod. Hypophos.]

About 2 grains each of calcium and sodium hypophosphites, with hypophosphorous acid, sugar and water, are contained in 1 fluidrachm of the finished syrup.

The *dose* is one fluidrachm (4 mils).

SYRUPUS CALCII HYDROCHLOROPHOSPHATIS. N. F. Syrupus Calcii Chlohydrophosphatis, N. F. III

Syrup of Calcium Hydrochlorophosphate [Syr. Calc. Hydrochlorophos.]

It is made from precipitated calcium phosphate, tincture of lemon peel, hydrochloric acid, water, and syrup. About 1 grain of calcium phosphate is contained in 1 fluidrachm of the finished syrup.

The *dose* is one fluidrachm (4 mils).

SYRUPUS CALCII HYPOPHOSPHITIS. N. F.

Syrup of Calcium Hypophosphite [Syr. Calc. Hypophos.]

It is made from calcium hypophosphite, hypophosphorous acid, sugar, and water. About 2 grains of calcium hypophosphite are contained in 1 fluidrachm of the finished syrup.

The *dose* is one fluidrachm (4 mils).

SYRUPUS CALCII IODIDI. N. F.

Syrup of Calcium Iodide [Syr. Calc. Iodid.]

It is made from iodine, iron wire, precipitated calcium carbonate, sugar, distilled water, and syrup. About 5 grains of calcium iodide are contained in 1 fluidrachm of the finished syrup. This may be used for the same purpose as the other iodides, but is by some believed to be especially valuable in *asthma.*

The *dose* is thirty minims (2 mils).

SYRUPUS CALCII LACTOPHOSPHATIS ET FERRI. N. F. Syrupus Calcii Lactophosphatis cum Ferro, N. F. III

Syrup of Calcium Lactophosphate and Iron [Syr. Calc. Lactophos. et Ferr.]

It is made from ferrous lactate, potassium citrate, water, and syrup of calcium lactophosphate. About ½ grain of ferrous lactate and ¼ grain of calcium lactate are contained in 1 fluidrachm of the finished syrup. Used as an alterative and tonic.

The *dose* is one fluidrachm (4 mils).

SYRUPUS CIMICIFUGÆ COMPOSITUS. N. F. Syrupus Actææ Compositus, N. F. III

Compound Syrup of Cimicifuga [Syr. Cimicif. Co. Compound Syrup of Actæa]

One fluidrachm (4 mils) of this syrup represents 2½ minims of fluidextract of cimicifuga, 1¼ minim, each, of fluidextracts of licorice and senega, 3-5th minim of fluidextract of ipecac and 2½ grains of wild cherry bark.

The *dose* is one fluidrachm (4 mils).

SYRUPUS CINNAMOMI. N. F.

Syrup of Cinnamon [Syr. Cinnam.]

It is made from Saigon cinnamon, alcohol, sugar, and cinnamon water. This is a mild astringent and carminative, useful, in connection with more potent remedies, in *diarrhea.*

The *dose* is one fluidrachm (4 mils).

SYRUPUS CODEINÆ. N. F.

Syrup of Codeine [Syr. Codein.]

It is made from codeine sulphate and syrup. About ⅛ grain of codeine sulphate is contained in 1 fluidrachm of the finished syrup. Used as a sedative.

The *dose* is one fluidrachm (4 mils).

SYRUPUS ERIODICTYI AROMATICUS. N. F.

Aromatic Syrup of Eriodictyon [Syr. Eriodict. Arom. Aromatic Syrup of Yerba Santa. Syrupus Corrigens]

It is made from fluidextract of eriodictyon, solution of potassium hydroxide, compound tincture of cardamom, the oils of sassafras, lemon, and clove, alcohol, sugar, and water. Used as a vehicle, especially for quinine.

The *dose* is two fluidrachms (8 mils).

SYRUPUS FERRI ET MANGANI IODIDI. N. F.

Syrup of Iron and Manganese Iodide [Syr. Ferr. et Mangan. Iod.]

It is made from iodine, iron wire, manganese sulphate, potassium iodide, sugar, diluted alcohol, and water. About 6 grains of ferrous iodide and 2¼ grains of manganese iodide are contained in 1 fluidrachm of finished syrup. Used as a chalybeate.

The *dose* is fifteen minims (1 mil).

SYRUPUS FERRI HYPOPHOSPHITIS. N. F.

Syrup of Ferric Hypophosphite [Syr. Ferr. Hypophos.]

It is made from ferric hypophosphite, potassium citrate, orange flower water, and syrup. About 1 grain of ferric hypophosphite is contained in 1 fluidrachm of finished syrup. Used as a tonic.

The *dose* is one fluidrachm (4 mils).

SYRUPUS FERRI LACTOPHOSPHATIS. N. F.

Syrup of Iron Lactophosphate [Syr. Ferr. Lactophos.]

The syrup is made from ferrous lactate, phosphoric acid, water, and syrup. About 1 grain of ferrous lactate or about 1½ grains of so-called lactophosphate of iron is represented in 1 fluidrachm of the finished syrup. Used as a chalybeate.

The *dose* is one fluidrachm (4 mils).

SYRUPUS FERRI PROTOCHLORIDI. N. F.

Syrup of Ferrous Chloride [Syr. Ferr. Protochlor. Syrup of Protochloride of Iron]

It is made from solution of ferrous chloride, glycerin, orange flower water and syrup. About 1 grain of ferrous chloride is contained in 1 fluidrachm of the finished syrup. Used as a tonic.

The *dose* is one fluidrachm (4 mils).

SYRUPUS FERRI, QUININÆ ET STRYCHNINÆ PHOSPHATUM. N. F. (Replacing U. S. P. VIII)

Syrup of the Phosphates of Iron, Quinine, and Strychnine [Syr. Ferr. Quin. et Strych. Phos.]

One fluidrachm (4 mils) of this syrup contains 1⅛ grains (0.08 Gm.) of ferric phosphate, 1½ grains (0.1 Gm.) of quinine, and 1-80th grain (0.0008 Gm.) of strychnine, with phosphoric acid, glycerin, water, and syrup. Used as a nerve tonic and hematinic.

The *dose* is one fluidrachm (4 mils).

SYRUPUS FERRI SACCHARATI SOLUBULIS. N. F.

Syrup of Soluble Saccharated Iron [Syr. Ferr. Sacch. Sol. Syrupus Ferri Oxydati Solubilis. Syrup of Saccharated Oxide of Iron. Syrup of Soluble Oxide of Iron]

It is made from distilled water and syrup. About 1 grain of metallic iron is represented in 75 minims of this syrup. Used as a tonic and chalybeate.

The *dose* is one fluidrachm (4 mils).

SYRUPUS FICORUM COMPOSITUS. N. F.

Compound Syrup of Figs [Syr. Ficor. Co.]

This syrup is prepared from figs, fluidextract of senna, aromatic fluidglycerate of cascara sagrada, oil of fennel, spirit of peppermint, sugar, and water. It is used as a laxative.

The *dose* is one fluidrachm (4 mils).

SYRUPUS GLYCYRRHIZÆ. N. F.

Syrup of Glycyrrhiza [Syr. Glycyrrh. Syrup of Licorice]

It is made from fluidglycerate of licorice and syrup. About 15 grains of glycyrrhiza root are represented in 1 fluidrachm of the finished syrup. It is used as vehicle.

The *dose* is two fluidrachms (8 mils).

SYRUPUS HYPOPHOSPHITUM COMPOSITUS. N. F. (Replacing U. S. P. VIII)

Compound Syrup of Hypophosphites [Syr. Hypophos. Co.]

One fluidrachm (4 mils) of this preparation contains 2 grains (0.13 Gm.) of calcium hypophosphite, one grain (0.065 Gm.) each of potassium and sodium hypophosphites, ⅛ grain (0.008 Gm.) each of ferric and manganese hypophosphites, 1-16th grain (0.004 Gm.) of quinine, and 1-160th grain (0.0004 Gm.) of strychnine with sodium citrate, diluted hypophosphorous acid, in a vehicle of glycerin and syrup. The formula is practically identical with that

of the U. S. P. VIII; the sugar was slightly reduced and 5 per cent. of glycerin was added. It is a widely prescribed, but useless, concoction.

The *dose* is two fluidrachms (8 mils).

SYRUPUS IODOTANNICUS. N. F.

Syrup of Iodotannin [Syr. Iodotan.]

This syrup contains 0.27 per cent. of iodine and 0.54 per cent. of tannin. It is used as an alterative and astringent.

The *dose* is one fluidrachm (4 mils).

SYRUPUS IPECACUANHÆ ET OPII. N. F.

Syrup of Ipecac and Opium [Syr. Ipecac. et Opii. Syrup of Dover's Powder]

It is made with the official tincture of ipecac and opium, with spirit of cinnamon, cinnamon water, and syrup. Five grains of Dover's powder are represented by 1 fluidrachm of finished syrup. It is used as a diaphoretic and sedative.

The *dose* is one fluidrachm (4 mils).

SYRUPUS KRAMERIÆ. N. F. (U. S. P. VIII)

Syrup of Krameria [Syr. Kramer.]

This is made with 45 per cent. fluidextract of krameria and syrup. The formula is the same as that of the U. S. P. VIII. It is used as an intestinal astringent.

The *dose* is one fluidrachm (4 mils).

SYRUPUS MANNÆ. N. F.

Syrup of Manna [Syr. Mann.]

This syrup contains about 12.5 per cent. of manna, with sugar, alcohol, and water. Used as a laxative in a *dose* of two fluidrachms (8 mils).

SYRUPUS MORPHINÆ ET ACACIÆ. N. F. Syrupus Pectoralis, N. F. III

Syrup of Morphine and Acacia [Syr. Morph. et Acac. Jackson's Pectoral Syrup]

This is made from morphine hydrochloride, oil of sassafras, and syrup of acacia. About 1-32nd grain of morphine hydrochloride is contained in 1 fluidrachm of the finished syrup. It is pectoral and sedative.

The *dose* is one fluidrachm (4 mils).

SYRUPUS PAPAVERIS. N. F.

Syrup of Poppy [Syr. Papaver.]

This syrup is now prepared from poppy capsules. One fluidrachm (4 mils) represents 6 grains (0.4 Gm.) of the drug. It is used as an anodyne and sedative, the *dose* being one fluidrachm (4 mils).

SYRUPUS PHOSPHATUM COMPOSITUS. N. F.

Compound Syrup of the Phosphates [Syr. Phos. Co. Chemical Food]

This syrup represents 50 per cent., by volume, of compound solution of the phosphates in a vehicle of glycerin and syrup colored with cudbear. It is probably destitute of medicinal value.

Dose, one fluidrachm (4 mils).

SYRUPUS PHOSPHATUM CUM QUININA ET STRYCHNINA. N. F. Syrupus Hydrochlorophosphatum, N. F. III

Syrup of Phosphates with Quinine and Strychnine [Syr. Phos. c. Quin. et Strych. Compound Syrup of Hydrochlorophosphates]

One fluidrachm (4 mils) of this syrup represents ¼ grain (0.015 Gm.) of quinine hydrochloride, 1-120th grain (0.0056 Gm.) of strychnine nitrate with uncolored compound syrup of the phosphates. It is used as a bitter tonic in the *dose* of one fluidrachm (4 mils).

SYRUPUS PINI STROBI COMPOSITUS. N. F.

Compound Syrup of White Pine [Syr. Pin. Strob. Co.]

This syrup is made from white pine bark, wild cherry bark, aralia, balsam poplar buds, sanguinaria, sassafras, cudbear, chloroform, oil of sassafras, sugar, alcohol, water, and syrup. It is used as an expectorant and sedative in the *dose* of one fluidrachm (4 mils).

SYRUPUS PINI STROBI COMPOSITUS CUM MORPHINA. N. F. Syrupus Pini Strobi Compositus, N. F. III

Compound Syrup of White Pine with Morphine [Syr. Pin. Strob. c. Morph.]

This syrup is made by dissolving 0.4 Gm. of morphine sulphate in 1000 mils of compound syrup of white pine. It contains, therefore, about one-fortieth grain of morphine in each fluidrachm.

The *dose* is thirty minims (2 mils).

SYRUPUS QUINIDINÆ. N. F.

Syrup of Quinidine [Syr. Quinid. Bitterless Syrup of Quinidine]

It is made from quinidine, oil of orange, and syrup. About 2 grains of quinidine is contained in 1 fluidrachm of finished syrup. Used

as a tonic and antiperiodic. Shake well before dispensing.

The *dose* is one fluidrachm (4 mils).

SYRUPUS RHAMNI CATHARTICÆ. N. F.

Syrup of Rhamnus Cathartica [Syr. Rham. Cathart. Syrup of Buckthorn Berries. Syrupus Spinæ Cervinæ]

This syrup contains 20 per cent. of fluidextract of buckthorn berries with 0.02 per cent. each of oils of fennel and cinnamon in syrup. It is used as a cathartic in two fluidrachms (8 mil) *doses*.

SYRUPUS ROSÆ. N. F. (U. S. P. VIII)

Syrup of Rose [Syr. Ros.]

This syrup is made with 12.5 per cent. of fluidextract of rose and 1 per cent. diluted sulphuric acid. The formula is the same as that of the U. S. P. VIII. It is used as a flavoring vehicle.

SYRUPUS RUBI. N. F. (U. S. P. VIII)

Syrup of Rubus [Syr. Rubi]

This syrup contains 25 per cent. of fluidextract of rubus with syrup. The formula is the same as that of the U. S. P. VIII. It is used as an astringent.

The *dose* is one fluidrachm (4 mils).

SYRUPUS RUBI FRUCTUS. N. F.

Syrup of Blackberry Fruit [Syr. Rubi. Fruct.]

This syrup is made from fresh ripe blackberries. It is kept in paraffin-sealed bottles. Used as a vehicle and astringent.

SYRUPUS RUBI IDÆI. N. F.

Syrup of Raspberry [Syr. Rubi Id.]

This syrup is made from fresh ripe raspberries and stored in thoroughly cleaned, wax sealed bottles. Used as a vehicle.

SYRUPUS SANGUINARIÆ. N. F.

Syrup of Sanguinaria [Syr. Sanguinar. Syrup of Bloodroot]

It is made from powdered sanguinaria, acetic acid, sugar, and water. Each fluidrachm represents about 13 grains of sanguinaria. Used as an expectorant.

The *dose* is thirty minims (2 mils).

SYRUPUS SENNÆ AROMATICUS. N. F.

Aromatic Syrup of Senna [Syr. Senn. Arom.]

It is made from fluidextract of senna, with jalap, rhubarb, cinnamon, clove, nutmeg, oil of lemon, sugar, and diluted alcohol. About 7½ grains of senna, 3 grains of jalap, and 1 grain of rhubarb are contained in 1 fluidrachm of finished syrup. Used as a purgative.

The *dose* is two fluidrachms (8 mils).

SYRUPUS SENNÆ COMPOSITUS. N. F.

Compound Syrup of Senna [Syr. Senn. Co.]

It is made from the fluidextracts of senna, rhubarb, and frangula, methyl salicylate, alcohol, and syrup. About 8 grains of senna and 2 grains each of rhubarb and frangula are represented in 1 fluidrachm of the finished syrup. Used as a purgative.

The *dose* is two fluidrachms (8 mils).

SYRUPUS SODII HYPOPHOSPHITIS. N. F.

Syrup of Sodium Hypophosphite [Syr. Sod. Hypophos.]

It is made from sodium hypophosphite, hypophosphorous acid, sugar, and water. Two grains of sodium hypophosphite are represented by 1 fluidrachm of finished syrup. Used as an alterative.

The *dose* is one fluidrachm (4 mils).

SYRUPUS STILLINGIÆ COMPOSITUS. N. F.

Compound Syrup of Stillingia [Syr. Stilling. Co.]

It is made from compound fluidextract of stillingia, sugar, and water. About 15 minims of compound fluidextract of stillingia are represented by 1 fluidrachm of the finished syrup. A relic of ancient superstition.

The *dose* is one fluidrachm (4 mils).

TINCTURA ALOES ET MYRRHÆ. N. F. (U. S. P. VIII)

Tincture of Aloes and Myrrh [Tr. Aloe. et Myrrh.]

This tincture is made with 10 per cent. each of aloes, myrrh, and licorice in 750 mils of alcohol and 250 mils of water. The formula is the same as that of the U. S. P. VIII. It is used as a purgative and emmenagogue.

The *dose* is thirty minims (2 mils).

TINCTURA AMARA. N. F.

Bitter Tincture [Tr. Amar. Stomachic Tincture. Bitter Stomachic Drops. Stomach Drops]

It is made from gentian, centaury, bitter orange peel, zedoary, two volumes of alcohol,

and one volume of water, being used as the menstruum. It is a bitter tonic.

The *dose* is thirty minims (2 mils).

TINCTURA ANTIPERIODICA. N. F.

Antiperiodic Tincture [Tr. Antiperiod. Warburg's Tincture]

This tincture is made from rhubarb, angelica fruit, elecampane, saffron, fennel, gentian, zedoary, cubeb, myrrh, camphor, white agaric, black pepper, cinnamon, ginger, quinine bisulphate, and extract of aloes, three volumes of alcohol, and two volumes of water, being used as the menstruum. About 9 grains of quinine bisulphate are contained in 1 fluidounce of finished tincture.

Dosage.—The dosage of Warburg's tincture depends on the kind used—whether with aloes or without—and the intended purpose, and varies from one fluidrachm (4 mils) to four fluidrachms (16 mils). The larger quantity is given when Dr. Warburg's original directions are followed for administering the remedy in remittent fevers, which were as follows: "One-half ounce to be given alone without dilution, after the bowels have been evacuated by any convenient purgative, all drink being withheld. After three hours, another half ounce is to be given." It is an antiperiodic.

TINCTURA ANTIPERIODICA SINE ALOE. N. F.

Antiperiodic Tincture without Aloes [Tr. Antiperiod. s. Aloe. Warburg's Tincture without Aloes]

This is made as directed under *Tinctura Antiperiodica*, omitting the extract of aloes.

For dosage, see *Tinctura Antiperiodica.*

TINCTURA AROMATICA. N. F.

Aromatic Tincture [Tr. Arom.]

This tincture is made from cinnamon, ginger, galangal, clove, cardamom, two volumes of alcohol, and one volume of water being used as the menstruum. It is used as a carminative and aromatic.

The *dose* is thirty minims (2 mils).

TINCTURA BRYONIÆ. N. F.

Tincture of Bryonia [Tr. Bryon.]

This tincture is made by maceration and subsequent percolation, using 10 per cent. bryonia and alcohol. It is used as an alterative and hydragogue cathartic.

The *dose* is one fluidrachm (4 mils).

TINCTURA CACTI GRANDIFLORI. N. F.

Tincture of Cactus Grandiflorus [Tr. Cact. Grand.]

This tincture is made from 50 per cent. cactus grandiflorus and alcohol by maceration and expression and further percolation of this marc. It is supposed by some to act as a regulator of cardiac arrythmias.

The *dose* is fifteen minims (1 mil).

TINCTURA CALENDULÆ. N. F. (U. S. P. VIII)

Tincture of Calendula [Tr. Calend.]

This tincture is made by maceration with 20 per cent. calendula and alcohol. The formula is the same as that of the U. S. P. VIII. Used as an antiseptic and discutient.

TINCTURA CAPSICI ET MYRRHÆ. N. F.

Tincture of Capsicum and Myrrh [Tr. Capsic. et Myrrh. Hot Drops. Thomsonian Number Six]

It is made from capsicum, myrrh, nine volumes of alcohol, and one volume of water being used as the menstruum. It is a powerful gastric stimulant and carminative.

The *dose* is thirty minims (2 mils).

TINCTURA CARAMELLIS. N. F.

Tincture of Caramel

This tincture contains 10 per cent. of caramel in 25 per cent. alcohol. Used as a coloring agent.

TINCTURA CIMICIFUGÆ. N. F. (U. S. P. VIII)

Tincture of Cimicifuga [Tr. Cimicif.]

This tincture is made by maceration and subsequent percolation with alcohol. It contains 20 per cent. of cimicifuga. The formula is the same as that of the U. S. P. VIII. Used as an alterative and sedative.

The *dose* is one fluidrachm (4 mils).

TINCTURA COCCULI INDICI. N. F.

Tincture of Cocculus Indicus [Tr. Coccul. Ind.]

This tincture is made from 10 per cent. powdered fishberries with diluted alcohol by maceration and subsequent percolation.

This tincture is used almost exclusively for external application to destroy parasites.

TINCTURA CROCI. N. F.

Tincture of Saffron [Tr. Croc.]

This tincture is made from saffron, 10 per cent., in diluted alcohol, prepared by maceration and subsequent percolation. Used as coloring and flavoring agent.

TINCTURA CUBEBÆ. N. F.

Tincture of Cubeb [Tr. Cubeb.]

This tincture is made from cubeb, 20 per cent., in alcohol, by maceration and subsequent percolation. Used as a diuretic and carminative.

The *dose* is one fluidrachm (4 mils).

TINCTURA DELPHINII. N. F.

Tincture of Larkspur [Tr. Delphin.]

This tincture is made from 10 per cent. larkspur seed in alcohol, made by maceration and subsequent percolation.

This tincture is rarely used internally, but is commonly employed externally to destroy body vermin.

TINCTURA ERGOTÆ AMMONIATA. N. F.

Ammoniated Tincture of Ergot [Tr. Ergot. Ammon.]

This tincture is made from ergot, 25 per cent., ammonia water, 10 per cent., and water and alcohol. Made by maceration and subsequent percolation. Used as a hemostatic and parturient.

The *dose* is one fluidrachm (4 mils).

TINCTURA FERRI CHLORIDI ÆTHEREA. N. F.

Ethereal Tincture of Ferric Chloride [Tr. Ferr. Chlor. Æth. Bestuscheff's Tincture. Lamotte's Drops]

It is made from solution of ferric chloride, ether, and alcohol. Used as a chalybeate.

The *dose* is thirty minims (2 mils).

TINCTURA FERRI CITRO-CHLORIDI. N. F.

Tincture of Ferric Citro-Chloride [Tr. Ferr. Citro-Chlor. Tasteless Tincture of Ferric Chloride. Tasteless Tincture of Iron]

This tincture contains 35 per cent. of solution of ferric chloride with sodium citrate, alcohol and water. Used as a chalybeate.

The *dose* is eight minims (0.5 mil).

TINCTURA FERRI POMATA. N. F.

Tincture of Ferrated Extract of Apples [Tr. Ferr. Pomat. Tinctura Ferri Malatis Crudi. Tincture of Crude Malate of Iron]

This tincture is made from ferrated extract of apples, alcohol, and cinnamon water. Used as a chalybeate.

The *dose* is one fluidrachm (4 mils).

TINCTURA GALLÆ. N. F. (Replacing U. S. P. VIII)

Tincture of Nutgall [Tr. Gall.]

This tincture is made from nutgall, 20 per cent., and glycerin, 10 volumes, in alcohol. Made by maceration, instead of the percolation of the U. S. P. VIII. The menstruum was not changed. Used as an astringent. The *dose* is one fluidrachm (4 mils).

TINCTURA GUAIACI COMPOSITA. N. F.

Compound Tincture of Guaiac [Tr. Guaiac. Co. Dewee's Tincture of Guaiac]

This tincture is made from guaiac, potassium carbonate, pimenta, pumice, alcohol, water, and diluted alcohol. Used for rheumatism, and as an emmenagogue.

The *dose* is one fluidrachm (4 mils).

TINCTURA HUMULI. N. F.

Tincture of Hops [Tr. Humul.]

This tincture is made from hops, 20 per cent., in diluted alcohol. Made by maceration and subsequent percolation. Used as a sedative and bitter tonic.

The *dose* is one fluidrachm (4 mils).

TINCTURA IGNATIÆ. N. F.

Tincture of Ignatia [Tr. Ignat.]

This tincture is made from ignatia, 10 per cent., alcohol, eight volumes, and water one volume. An assay is provided in the text which states that 100 mils of the tincture should yield not less than 0.18 Gm. nor more than 0.22 Gm. of alkaloids of ignatia. Its uses are similar to those of Tincture of Nux Vomica.

The *dose* is ten minims (0.6 mil).

TINCTURA IODI DECOLORATA. N. F.

Decolorized Tincture of Iodine [Tr. Iod. Decolor.]

This tincture is made from iodine, sodium thiosulphate, water, stronger ammonia water, and alcohol. Used as a discutient, but is of little value, as it consists chiefly of a solution of sodium and ammonium iodides.

TINCTURA IODI FORTIOR. N. F.

Tinctura Iodi Churchill, N. F. III. Stronger Tincture of Iodine [Tr. Iod. Fort. Churchill's Tincture of Iodine]

This tincture contains 16.5 Gm. of iodine and 3.3 Gm. of potassium iodide in each 100 mils. The solvent is about 70 per cent. alcohol. Used as a discutient and counter-irritant.

TINCTURA IPECACUANHÆ ET OPII. N. F. (U. S. P. VIII)

Tincture of Ipecac and Opium [Tr. Ipecac. et Opii. Tincture of Dover's Powder]

This tincture is made from tincture of deodorized opium, fluidextract of ipecac, and diluted alcohol, representing 10 per cent. each of deodorized opium and ipecac. Used as a diaphoretic and anodyne.

The *dose* is eight minims (0.5 mil).

TINCTURA JALAPÆ. N. F.

Tincture of Jalap [Tr. Jalap.]

This tincture is made from 20 per cent. of jalap, with alcohol and water. Used as a cathartic.

The *dose* is one fluidrachm (4 mils).

TINCTURA JALAPÆ COMPOSITA. N. F.

Compound Tincture of Jalap [Tr. Jalap. Co.]

It is made from 12.5 per cent. of jalap and 3.0 per cent. of scammony, with alcohol and water. Used as a purgative.

The *dose* is one fluidrachm (4 mils).

TINCTURA KINO ET OPII COMPOSITA. N. F. Tinctura Kino Composita, N. F. III

Compound Tincture of Kino and Opium [Tr. Kino et Opii Co. Compound Tincture of Kino]

The tincture is made from the tinctures of kino and opium, spirit of camphor, oil of clove, cochineal, aromatic spirit of ammonia and diluted alcohol. Used as an astringent and anodyne. One fluidrachm contains 6 minims of tincture of opium.

The *dose* is one fluidrachm (4 mils).

TINCTURA KRAMERIÆ. N. F. (U. S. P. VIII)

Tincture of Krameria [Tr. Kramer.]

This tincture is made from 20 per cent. of krameria and diluted alcohol. The formula is the same as that of the U. S.P. VIII. Used as an astringent and hemostatic.

The *dose* is one fluidrachm (4 mils).

TINCTURA OPII CROCATA. N. F.

Tincture of Opium with Saffron [Tr. Opii Crocat. Sydenham's Laudanum. Tinctura Opii Crocata P. I.]

This tincture is made from granulated opium, saffron, cinnamon, and clove, with diluted alcohol, made by maceration and subsequent percolation. An assay is provided. Used as a sedative and carminative.

The dose is ten minims (0.6 mil).

TINCTURA PARACOTO. N. F. Tinctura Coto, N. F. III

Tincture of Paracoto [Tr. Paracoto]

This tincture is made from coto bark (12.5 per cent.) and alcohol. Used in *diarrhea.*

The *dose* is thirty minims (2 mils).

TINCTURA PASSIFLORÆ. N. F.

Tincture of Passion Flower [Tr. Passiflor.]

This tincture is made from 20 per cent. passion flower and diluted alcohol. Used as an analgesic and anodyne.

The *dose* is ten minims (0.6 mil).

TINCTURA PECTORALIS. N. F.

Pectoral Tincture [Tr. Pectoral. Guttæ Pectorales. Pectoral Drops. Bateman's Pectoral Drops]

It is made from tincture of opium, compound tincture of gambir, spirit of camphor, oil of anise, caramel, and diluted alcohol. Although popularly known as "pectoral drops," it is more useful in intestinal than pectoral complaints.

The *dose* for infants is 10 minims (0.6 mil).

TINCTURA PERSIONIS. N. F.

Tincture of Cudbear [Tr. Persion.]

This tincture is made from cudbear (10 per cent.), alcohol, and water. Used as a bright red coloring agent.

TINCTURA PERSIONIS COMPOSITA. N. F.

Compound Tincture of Cudbear [Tr. Persion. Co.]

This tincture is made from cudbear (1.5 per cent.), caramel (10 per cent.), alcohol, and water. Used as a brownish-red coloring agent.

TINCTURA PIMPINELLÆ. N. F.

Tincture of Pimpinella [Tr. Pimpinel.]

This tincture contains 20 per cent. of pimpinella, with alcohol and water. Used as a diuretic and tonic.

The dose is one fluidrachm (4 mils).

TINCTURA PULSATILLÆ. N. F.

Tincture of Pulsatilla [Tr. Pulsatil.]

This tincture is made from 10 per cent. pulsatilla, three volumes of alcohol, and one volume of water. Used as an alterative and antispasmodic.

The *dose* is thirty minims (2 mils).

TINCTURA QUILLAJÆ. N. F. (U. S. P. VIII)

Tincture of Quillaja [Tr. Quillaj.]

This tincture is made from 20 per cent. of quillaja, extracted with boiling water, the liquid concentrated and 35 per cent. of alcohol added. The process is the same as that of the U. S. P. VIII. Used chiefly as an emulsifying agent.

TINCTURA RHEI AQUOSA. N. F.

Aqueous Tincture of Rhubarb [Tr. Rhei Aq.]

This tincture is made from 10 per cent. rhubarb, with potassium carbonate, cinnamon water, alcohol, and water. Used as a cathartic.

The dose is one fluidrachm (4 mils).

TINCTURA RHEI DULCIS. N. F.

Sweet Tincture of Rhubarb [Tr. Rhei Dulc.]

This tincture contains 10 per cent. rhubarb, 4 per cent. each, of licorice and anise, 1 per cent. of cardamom seed, 10 per cent. of glycerin in a hydroalcoholic menstruum. Used as a laxative and carminative.

The *dose* is thirty minims (2 mils).

TINCTURA RHEI ET GENTIANÆ. N. F.

Tincture of Rhubarb and Gentian [Tr. Rhei et Gent.]

This tincture is made from rhubarb, gentian, and diluted alcohol. Each fluidrachm represents about 4 grains of rhubarb and 1 grain of gentian. Used as a tonic and laxative.

The *dose* is one fluidrachm (4 mils).

TINCTURA SABAL ET SANTALI. N. F.

Tincture of Saw Palmetto and Santal [Tr. Sabal. et Santal.]

This tincture is made from sabal (20 per cent.), sandalwood (6.5 per cent.), and a hydroalcoholic menstruum. It is used as a urinary antiseptic and sedative.

The *dose* is one fluidrachm (4 mils).

TINCTURA SERPENTARIÆ. N. F. (U. S. P. VIII)

Tincture of Serpentaria [Tr. Serpent.]

This tincture is made from 20 per cent. serpentaria and two volumes of alcohol and one volume of water as the menstruum. The process is practically identical with that of the U. S. P. VIII. It is used as a tonic and antiperiodic.

The dose is one fluidrachm (4 mils).

TINCTURA SUMBUL. N. F.

Tincture of Sumbul [Tr. Sumbul]

This tincture is made from 10 per cent. sumbul with two volumes of alcohol and one volume of water. Used as an antispasmodic and nervine.

The *dose* is one fluidrachm (4 mils).

TINCTURA VANILLÆ. N. F. (U. S. P. VIII)

Tincture of Vanilla [Tr. Vanill.]

This tincture is made from 10 per cent. vanilla, sugar, and a hydroalcoholic menstruum. The N. F. has modified the directions of the U. S. P. VIII by directing preliminary maceration and extraction with alcohol. Used as a flavoring agent.

TINCTURA VIBURNI OPULI COMPOSITA. N. F.

Compound Tincture of Viburnum [Tr. Viburn. Opul. Co.]

This tincture is made from viburnum opulus, dioscorea, scullcap, clove, cinnamon, glycerin, alcohol, and water. Used as an antispasmodic.

The *dose* is one fluidrachm (4 mils).

TINCTURA ZEDOARIÆ AMARA. N. F.

Bitter Tincture of Zedoary [Tr. Zedoar. Amar. Compound Tincture of Zedoary]

This tincture is made from zedoary, aloes, rhubarb, gentian, agaric, and saffron, using glycerin, alcohol, and water as the menstruum. It is used as a tonic and laxative.

The *dose* is one fluidrachm (4 mils).

TINCTURÆ ÆTHEREÆ. N. F.

Ethereal Tinctures

In the general formula for ethereal tinctures the quantity of drug is 10 per cent. A

menstruum of one volume of ether and two volumes of alcohol is used. Percolate in the usual manner, but with proper precautions to avoid evaporation.

TINCTURÆ MEDICAMENTORUM RECENTIUM. N. F.

Tinctures of Fresh Drugs [Tincturæ Herbarum Recentium, U. S. P. VIII]

In the general formula for tinctures of fresh drugs 50 per cent. of the fresh drug is macerated with alcohol.

TROCHISCI CARBONIS LIGNI. N. F.

Troches of Charcoal [Troch. Carb. Lig.]

Each troche contains wood charcoal, 0.3 Gm. (4½ grains), flavored with vanillin. Used as an absorbent.

The *dose* is one troche.

TROCHISCI GAMBIR. N. F. (U. S. P. VIII)

Troches of Gambir [Troch. Gambir]

Each troche contains gambir, 1 grain (0.06 Gm.), flavored with oil of cinnamon. It differs in flavor and size from the U. S. P. VIII troche of the same name. Used as an astringent and antiseptic.

The *dose* is one troche.

TROCHISCI MENTHÆ PIPERITÆ. N. F.

Troches of Peppermint [Troch. Menth. Pip.]

Each troche contains $^1/_6$ minim (0.01 mil) of oil of peppermint. Used as a carminative.

The *dose* is one troche.

TROCHISCI PHENOLPHTHALEINI. N. F.

Troches of Phenolphthalein [Troch. Phenolphthal.]

Each troche contains 1 grain (0.06 Gm.) of phenolphthalein. It is flavored with vanillin and colored with carmine. Used as a laxative.

The *dose* is one troche.

TROCHISCI QUININÆ TANNATIS. N. F.

Troches of Quinine Tannate [Troch. Quin. Tan.]

Each troche contains quinine tannate, 1 grain (0.06 Gm.), combined with cacao butter, cocoa, sugar, vanillin, and sodium benzosulphinide.

Used as an antiperiodic, presenting quinine in an almost bitterless form.

The *dose* is one troche.

TROCHISCI SANTONINI. N. F. (Replacing U. S. P. VIII)

Troches of Santonin [Troch. Santonin.]

Each troche contains one-half grain (0.03 Gm.) of santonin and is flavored with cocoa and vanillin. It differs in flavor and size from the U. S. P. VIII Troche of the same name, but continues the error of directing the santonin to be in fine powder. Used as a vermifuge.

The *dose* is one troche.

TROCHISCI SANTONINI COMPOSITI. N. F.

Compound Troches of Santonin [Troch. Santonin. Co. Troches of Santonin and Calomel]

Equivalent to the preceding troche with an additional one-half grain (0.03 Gm.) of calomel. Used for the same purposes and in the same *dose.*

TROCHISCI SULPHURIS ET POTASSII BITARTRATIS. N. F.

Troches of Sulphur and Potassium Bitartrate [Troch. Sulphur et Pot. Bitart. Troches of Sulphur and Cream of Tartar]

Each troche contains four and one-half grains (0.3 Gm.) of washed sulphur, one grain (0.06 Gm.) of potassium bitartrate flavored with oil of orange. Used as an alterative and laxative.

The *dose* is one troche.

TROCHISCI ULMI. N. F.

Troches of Elm [Troch. Ulmi]

Each troche contains three grains (0.2 Gm.) of elm, flavored with methyl salicylate. Used as a demulcent.

The *dose* is one troche.

UNGUENTUM CALAMINÆ. N. F.

Calamine Ointment [Ung. Calamin. Unguentum Zinci Carbonatis Crudi. Unguentum Calaminare. Turner's Cerate]

It contains 17 parts of calamine, with 83 parts of ointment. This sedative protective ointment has properties similar to those of the ointment of zinc oxide, over which it has the advantage of being a pinkish color and hence not so conspicuous when applied to the skin.

UNGUENTUM CAMPHORÆ. N. F.

Camphor Ointment [Ung. Camph.]

It contains 22 per cent. of camphor, with white wax and lard. Used as an anodyne and counter-irritant.

UNGUENTUM FUSCUM. N. F.

Brown Ointment [Ung. Fusc. Unguentum Matris. Mother's Salve]

It contains 50 per cent. of camphorated brown plaster, with olive oil and suet, equal parts. Used as a discutient.

UNGUENTUM HYDRARGYRI OXIDI RUBRI. N. F. (U. S. P. VIII)

Ointment of Red Mercuric Oxide [Ung. Hydrarg. Oxid. Rub.]

This ointment is made with red mercuric oxide, 10 per cent., water, 10 per cent., hydrous wool fat and petrolatum, of each, 40 per cent. The formula is the same as that of the U. S. P. VIII. Used as an alterative and stimulant discutient.

UNGUENTUM PICIS COMPOSITUM. N. F.

Compound Tar Ointment [Ung. Pic. Co.]

It is made from oil of tar, tincture of benzoin, zinc oxide, yellow wax, lard, and cottonseed oil. It is used against parasites and in skin diseases.

UNGUENTUM PLUMBI IODIDI. N. F.

Ointment of Lead Iodide [Ung. Plumb. Iod.]

This ointment is made from lead iodide, 10 per cent., and benzoated lard, 90 per cent. Used as an alterative and discutient.

UNGUENTUM POTASSII IODIDI. N. F. (Replacing U. S. P. VIII)

Ointment of Potassium Iodide [Ung. Pot. Iod.]

This ointment should be freshly made with 10 Gm. potassium iodide, 1 Gm. sodium thiosulphate, 9 Gm. of water, and 80 Gm. benzoinated lard. The formula differs from that of the U. S. P. VIII. Used as a discutient and absorbent.

UNGUENTUM RESORCINOLIS COMPOSITUM. N. F.

Unguentum Resorcini Compositum, N. F. III. Compound Resorcinol Ointment [Ung. Resorcin Co.]

It contains 6 per cent. each of resorcinol, zinc oxide, bismuth subnitrate, and rectified oil of birch tar, with petrolatum, anhydrous wool fat, and glycerin. It is used as an antiseptic and astringent in skin diseases.

UNGUENTUM SULPHURIS ALKALINUM. N. F.

Alkaline Sulphur Ointment [Ung. Sulphur. Alk.]

This ointment is made with 20 Gm. sublimed sulphur, 10 Gm. of potassium carbonate, 5 mils water, and 65 Gm. benzoinated lard. Used as an antiparasitic and antipruritic.

UNGUENTUM SULPHURIS COMPOSITUM. N. F.

Compound Sulphur Ointment [Ung. Sulphur. Co. Wilkinson's Ointment. Hebra's Itch Ointment]

It contains 10 per cent. of precipitated calcium carbonate, 15 per cent. of sublimed sulphur, 15 per cent. of oil of cade, with soft soap and lard. Used in the treatment of itch.

UNGUENTUM VERATRINÆ. N. F. (U. S. P. VIII)

Veratrine Ointment [Ung. Veratrin.]

This ointment is made with veratrine, 4 Gm., expressed oil of almond, 6 Gm., and benzoinated lard, 90 Gm. The formula is the same as that of the U. S. P. VIII. Used as an anodyne and counter-irritant.

UNGUENTUM ZINCI STEARATIS. N. F. (U. S. P. VIII)

Ointment of Zinc Stearate [Ung. Zinc Stear.]

This ointment is made with zinc stearate, 50 Gm., and white petrolatum, 50 Gm. The U. S. P. VIII directed the incorporation of the melted zinc stearate, while the N. F. IV directs the incorporation of the zinc stearate without heat. It is used as a protective.

VINUM ANTIMONII. N. F. (Replacing U. S. P. VIII)

Wine of Antimony [Vin. Antimon.]

One fluidrachm of this wine represents one-fourth grain of antimony and potassium tartrate. The N. F. formula contains the same amount of antimony and potassium tartrate as that of the U. S. P. VIII, but sherry wine replaces the white wine. Used as a diaphoretic and emetic.

The *dose* is fifteen minims (1 mil).

VINUM AURANTII COMPOSITUM. N. F.

Compound Wine of Orange [Vin. Aurant. Co. Elixir Aurantiorum Compositum. Compound Elixir of Orange]

It is made from bitter orange peel, absinthium, menyanthes leaves, cascarilla, cinnamon, gentian, potassium carbonate, and sherry wine. One might well wish that this preparation had been omitted; its value as a bitter tonic in no way compares to its danger as an intoxicant.

The *dose* is one fluidrachm (4 mils).

VINUM CARNIS. N. F.

Wine of Beef [Vin. Carn. Beef and Wine]

This wine is made from extract of beef, hot water, syrup, alcohol, compound spirit of orange, and sherry wine. Two grains of extract of beef are represented in 1 fluidrachm of the finished wine. Contrary to the popular belief, this is *not* a nutrient, except for the sugar and alcohol in it.

The *dose* is two fluidrachms (8 mils).

VINUM CARNIS ET FERRI. N. F.

Wine of Beef and Iron [Vin. Carn. et Ferr. Beef, Wine, and Iron]

Two grains of extract of beef, and ⅔ grain of iron and ammonium citrate are represented in 1 fluidrachm of the finished wine. This is a popular, but therapeutically useless, tipple.

The *dose* is two fluidrachms (8 mils).

VINUM COLCHICI CORMI. N. F.

Vinum Colchici Radicis, N. F. III. Wine of Colchicum Corm [Vin. Colchic. Corm.]

Made from 40 per cent. colchicum corm, 15 per cent. of alcohol, in sherry wine. An assay is provided in the text. It is required that each 100 mils yield from 0.126 to 0.154 Gm. of colchicine.

The *dose* is ten minims (0.6 mil).

VINUM COLCHICI SEMINIS N. F. (U. S. P. VIII)

Wine of Colchicum Seed [Vin. Colch. Sem.]

This wine is made from 10 per cent. fluidextract of colchicum seed, and 15 per cent. of alcohol, in sherry wine. An assay is provided in the text. It differs from the U. S. P. VIII formula only in the use of sherry wine instead of white wine and in the introduction of an assay and standard. The rubric requires from 0.036 to 0.044 Gm. of colchicine in 100 mils.

The *dose* is thirty minims (2 mils).

VINUM FERRI. N. F. (U. S. P. VIII)

Wine of Iron [Vin. Ferr. Wine of Citrate of Iron]

This wine is made from 4 per cent. of iron and ammonium citrate, 6 per cent. tincture of sweet orange peel, syrup, and sherry wine. With the exception of the use of sherry wine instead of white wine it is the same as the U. S. P. VIII formula. Used as a hematinic and tonic.

The *dose* is two fluidrachms (8 mils).

VINUM FERRI AMARUM. N. F. (U. S. P. VIII)

Bitter Wine of Iron [Vin. Ferr. Amar.]

This wine contains about 5 per cent. of iron and quinine citrate, 6 per cent. of tincture of sweet orange peel, syrup, and sherry wine. With the exception of the use of sherry wine instead of white wine it is the same as the U. S. P. VIII formula. It is a hematinic and tonic.

Dose two fluidrachms (8 mils).

VINUM FRAXINI. N. F.

Vinum Fraxini Americanæ, N. F. III. Wine of White Ash [Vin. Frax.]

About 30 grains of white ash bark are represented in 1 fluidrachm of the finished wine. Used as a stimulant and emmenagogue.

The *dose* is one fluidrachm (4 mils).

VINUM IPECACUANHÆ. N. F. (U. S. P. VIII)

Wine of Ipecac [Vin. Ipecac.]

This wine is made from 10 per cent. fluidextract of ipecac, and 10 per cent. alcohol, in sherry wine. An assay is provided in the text. The rubric requires from 0.180 to 0.220 Gm. of ipecac alkaloids in 100 mils. The formula is the same as that of the U. S. P. VIII except that sherry wine replaces white wine and an assay and rubric are added. Used as an expectorant and emetic.

The *dose* is fifteen minims (1 mil).

VINUM PEPSINI. N. F.

Wine of Pepsin [Vin. Pepsin. Pepsin Wine]

It is made from glycerite of pepsin, alcohol and sherry wine. One grain of pepsin is represented in 1 fluidrachm of the finished wine. As pointed out elsewhere, alcohol prevents the enzymic action of pepsin; the proportion

of alcohol in this is sufficient to destroy the peptic ferment, hence it is useless.

The *dose* is two fluidrachms (8 mils).

VINUM PICIS. N. F.

Wine of Tar [Vin. Pic.]

This is a solution containing 10 per cent. of the soluble portion of tar in fortified sherry wine. It is useful as a stimulating expectorant.

Dose, two fluidrachms (8 mils).

VINUM PRUNI VIRGINIANÆ. N. F.

Wine of Wild Cherry [Vin. Prun. Virg.]

From 25 per cent. of wild cherry, water, alcohol (10 per cent.), sugar, and sherry wine. Used as a tonic and sedative.

The *dose* is one fluidrachm (4 mils).

VINUM PRUNI VIRGINIANÆ FERRATUM. N. F.

Ferrated Wine of Wild Cherry [Vin. Prun. Virg. Ferr.]

About 5 minims of tincture of citro-chloride of iron and 13 grains of wild cherry are represented by 1 fluidrachm of finished wine. Used as a chalybeate tonic.

The *dose* is one fluidrachm (4 mils).

VINUM RHEI COMPOSITUM. N. F. Tinctura Rhei Vinosa, N. F. III

Compound Wine of Rhubarb [Vin. Rhei Co.]

It is made from the fluidextracts of rhubarb and bitter orange peel, tincture of cardamom, sugar, and sherry wine. Used as a laxative and stomachic.

The *dose* is one fluidrachm (4 mils).
